ADRENAL GLAND

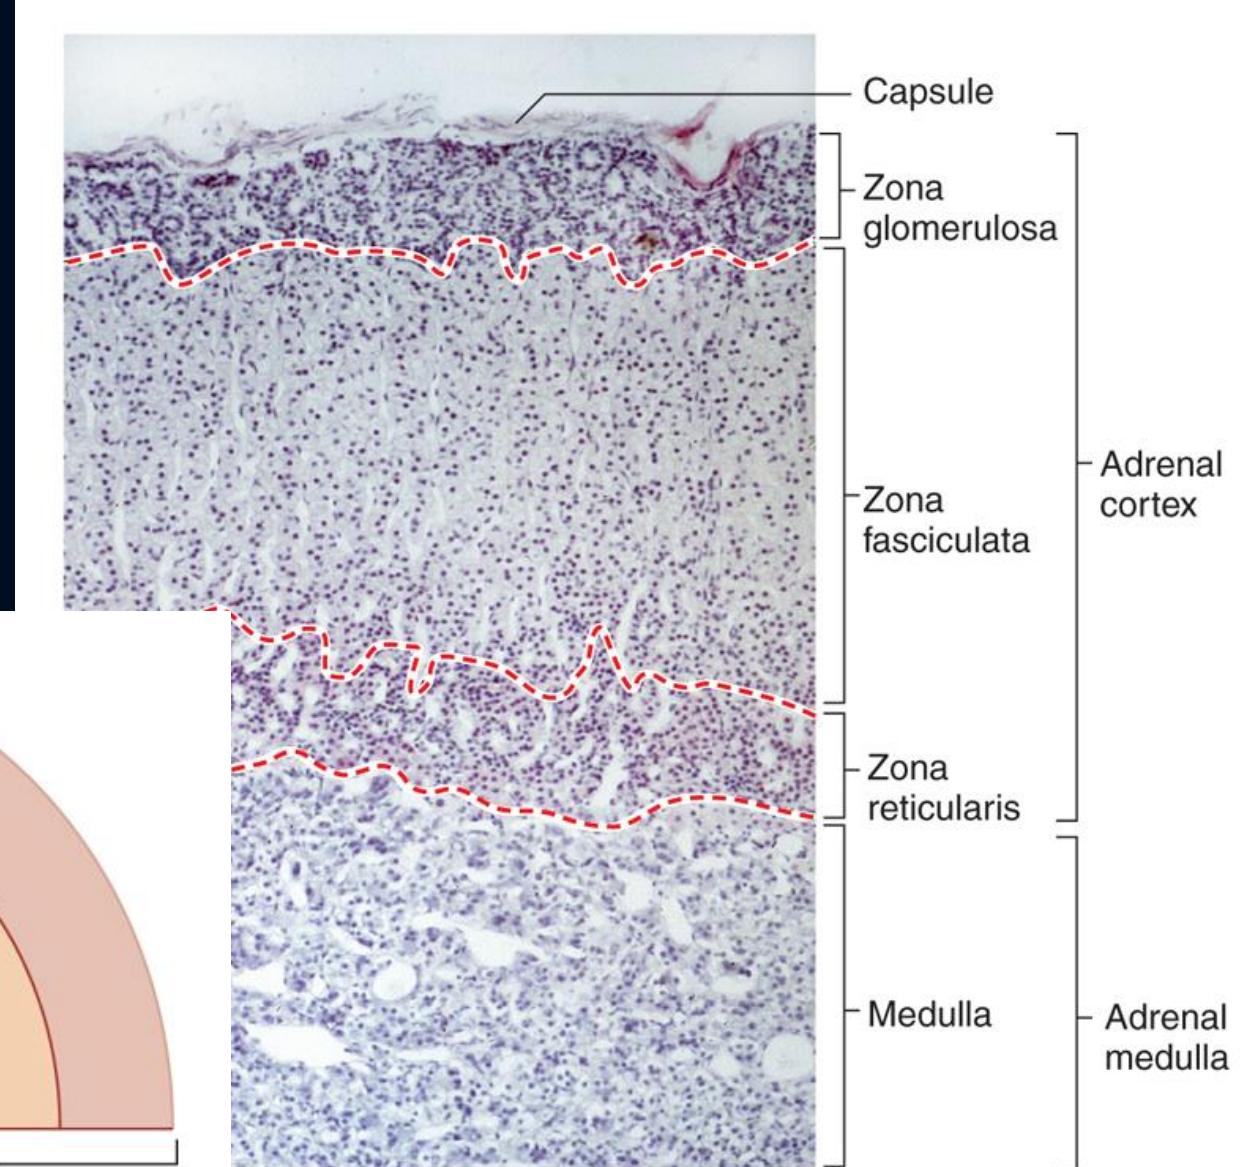

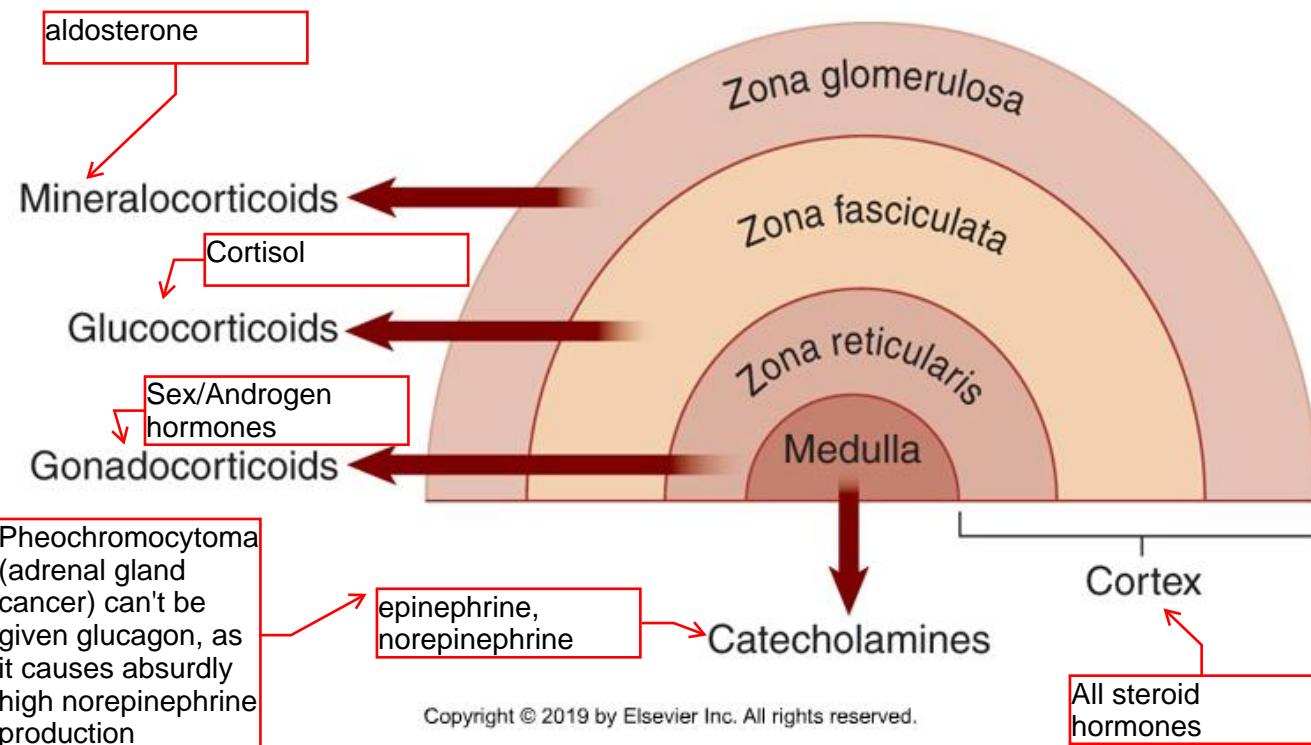

From Gosling J, Harris P, Whitmore I, Willan P: *Human anatomy*, ed 4, Philadelphia, 2002, Mosby.

# Adrenal Gland

# Cross section of adrenal gland

From Kierszenbaum A: *Histology and cell biology*, Philadelphia, 2002, Mosby.

# Mineralocorticoids (ie Aldosterone)

- What does it do?
  - Helps to regulate ECF volume by increasing reabsorption of Na<sup>+</sup> and H<sub>2</sub>O in nephron
  - Regulates ECF K<sup>+</sup> levels by increasing secretion of K<sup>+</sup> in nephron
- When is it released?
  - When Angiotensin II levels increase in blood
  - When ECF K<sup>+</sup> rises above its normal levels
  - When ACTH levels or ANP levels increase in Blood
- How does it work?
  - Epithelial Na<sup>+</sup> channels allow Na<sup>+</sup> to enter from lumen of nephron into cell
  - Epithelial K<sup>+</sup> channels allow K<sup>+</sup> to enter lumen from cell
  - Gradients maintained by Na<sup>+</sup> / K<sup>+</sup> pump
  - H<sub>2</sub>O follows the gradient

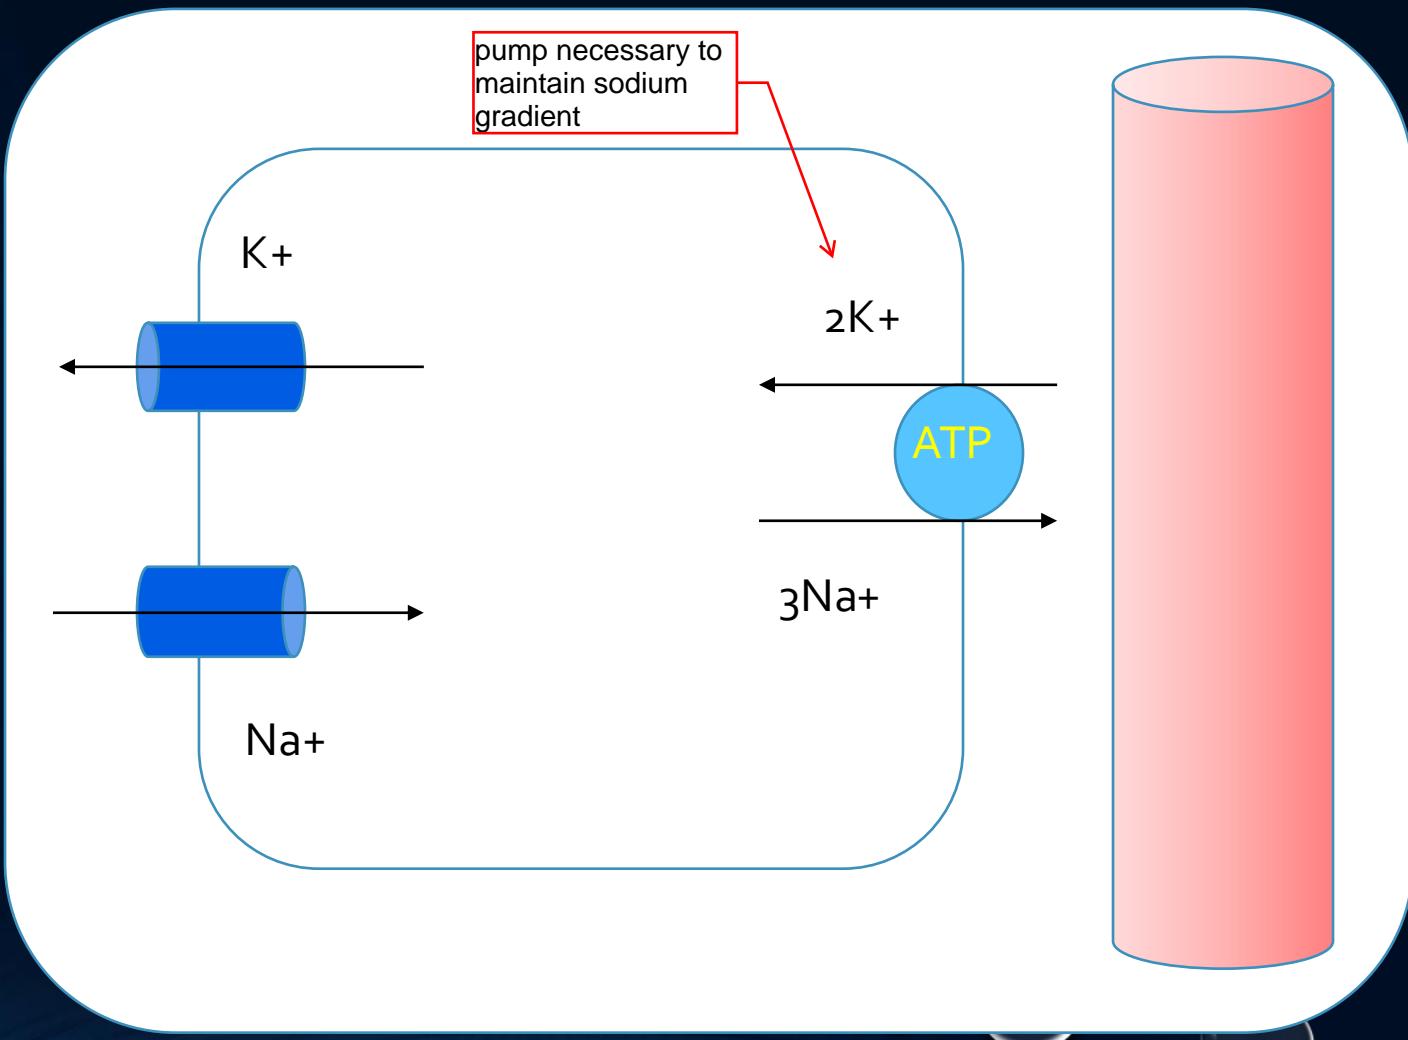

While ADH increases aquaporins, Aldosterone increases sodium channels, taking it and water out of urine.

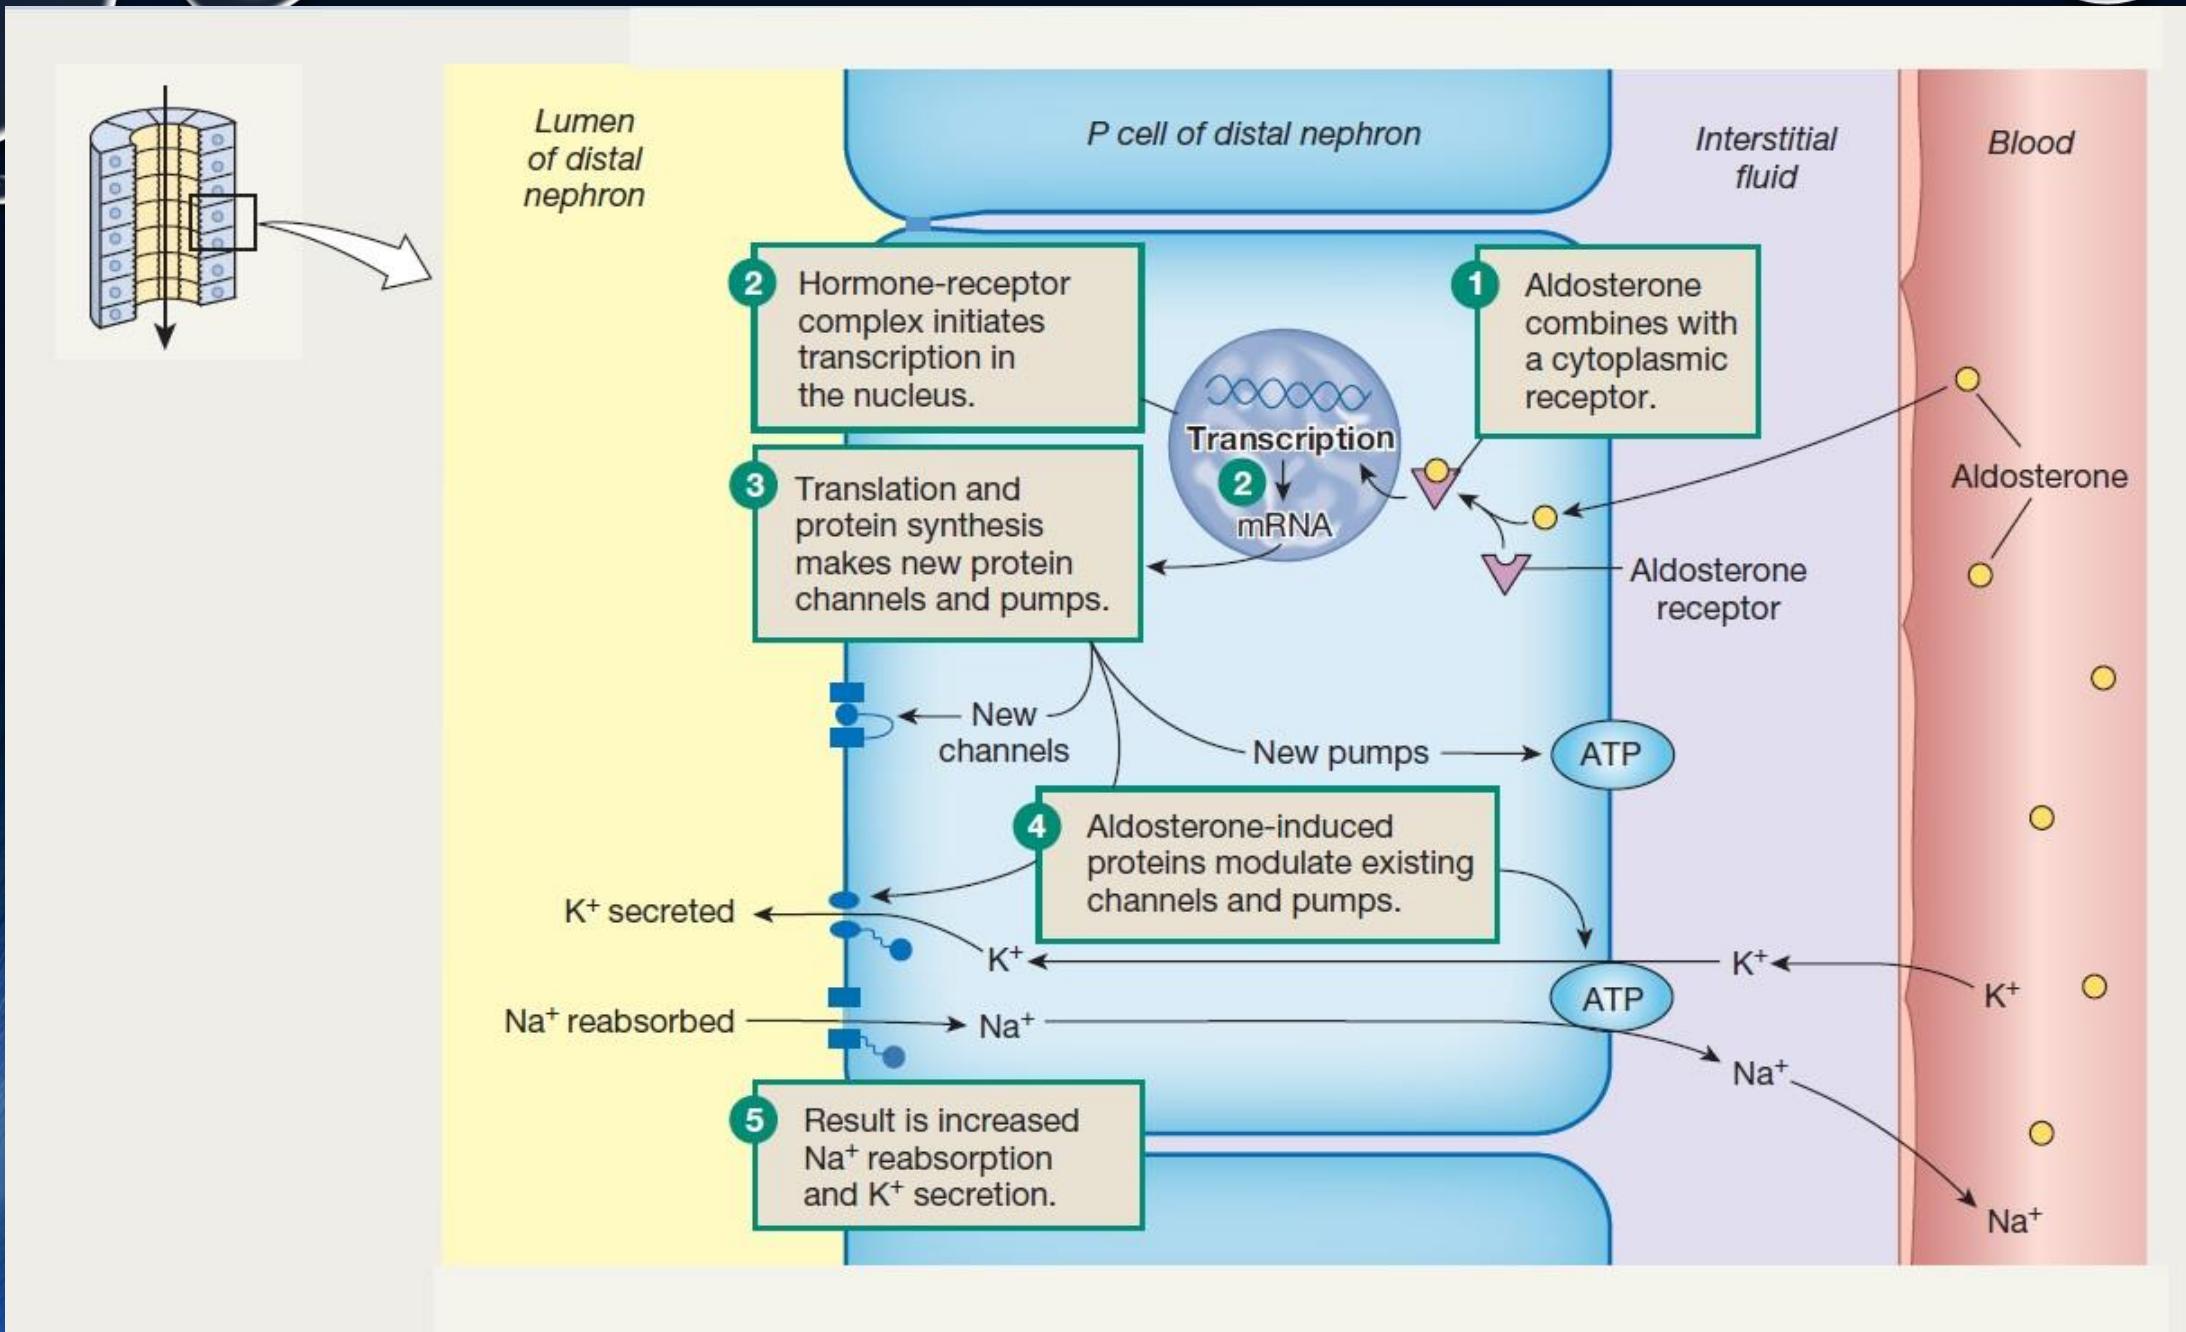

RAAS  
Renin Angiotensin Aldosterone System also releases aldosterone. Renin enzyme secreted by justaglomerular cells in response to low BP. These cells are at teh kidney gloemerulus, with plenty of blood to check pressure via neighbouring baroreceptors.

ACE inhibitors are common BP medications, as are Angiotensin receptor blocker. The former prevents angiotensin production, the latter prevents it from binding to receptors.

Renin converts Angioteninogen into angiotensin 1, circulating in the blood. In the lungs, angiotensin converting enzyme (ACE) converts it to angiotensin 2, which regulates BP via vasoconstriction and aldosterone release

# Effects of Aldosterone on Nephron Cells

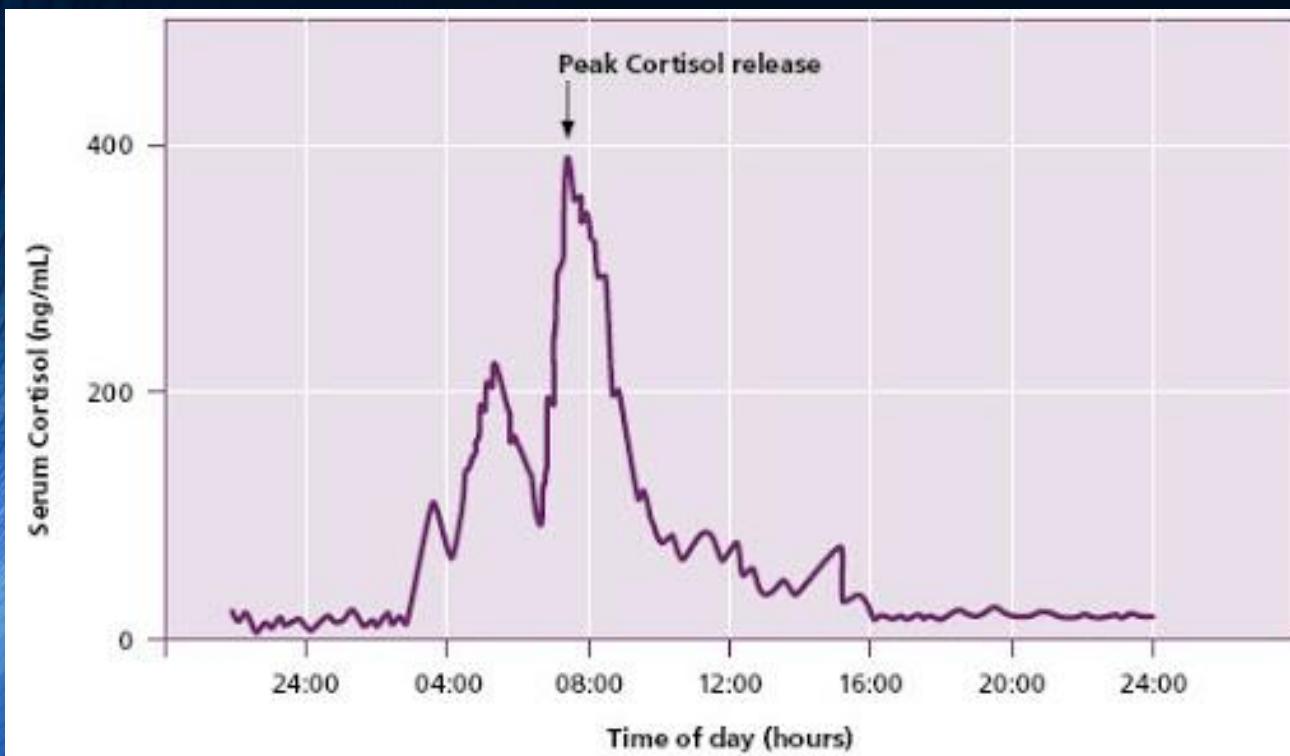

# Glucocorticoids – Cortisol

- What does it do?
  - Increases blood glucose, AA and FA by altering metabolism of fats and proteins
  - Gluconeogenesis
  - Vasoconstriction (increases BP)
  - Anti-inflammatory
- When is it released?
  - As part of stress response
  - Regular release related to circadian rhythms and negative feedback mechanisms

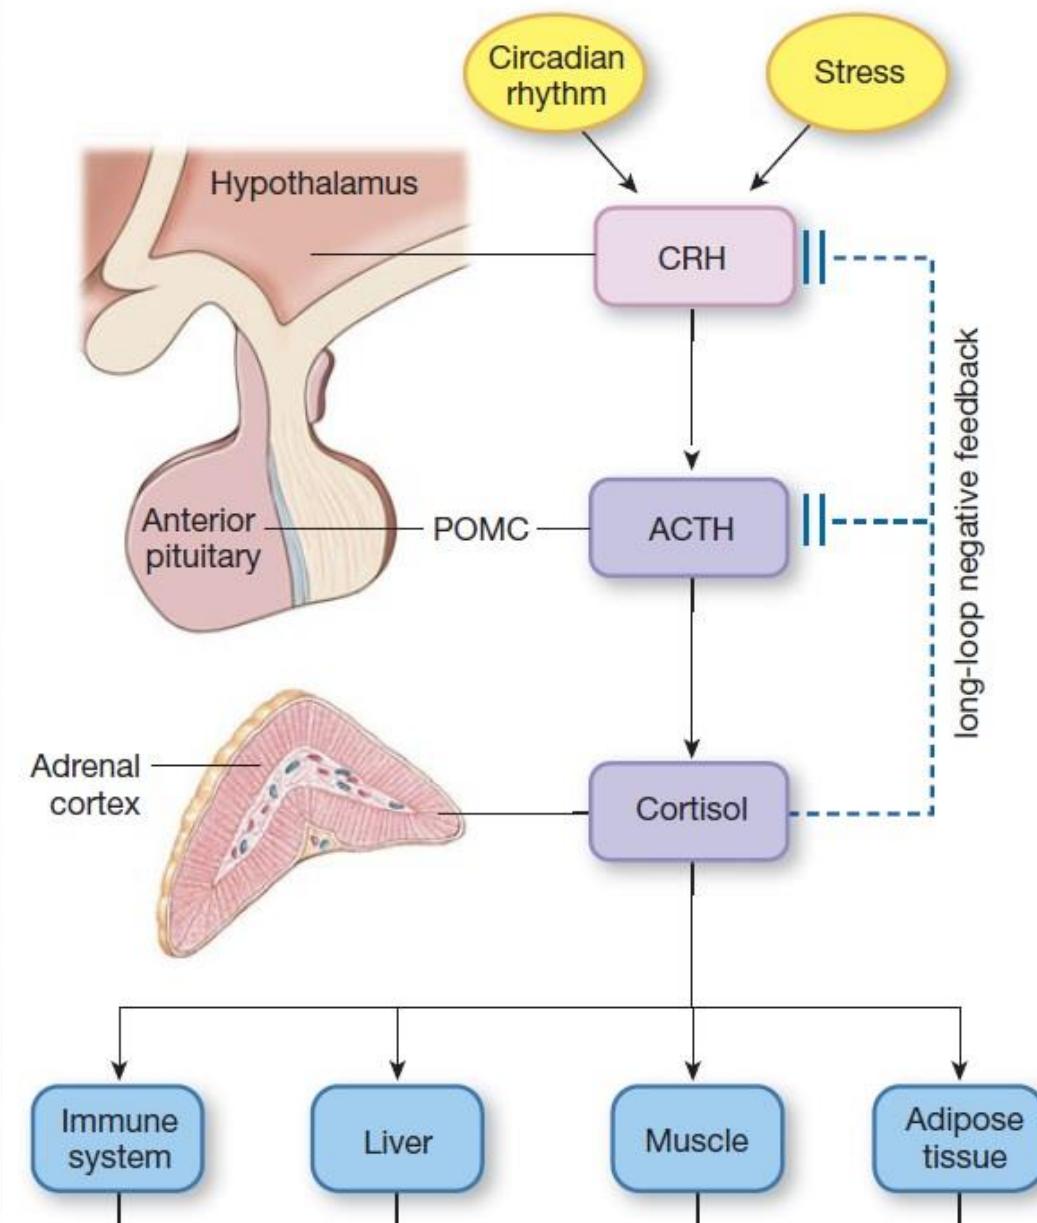

# Regulation Mechanisms

Short Loop Feedback  
Long Loop Feedback  
Circadian

## THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) PATHWAY

### (a) The control of cortisol secretion

# Cushing's Disease / Syndrome

Disease – due to body producing too much cortisol, possibly due to a tumour

Syndrome – due to overuse of cortisol / an iatrogenic cause

## Clinical Manifestations

Fat deposits – buffalo hump, moon face,

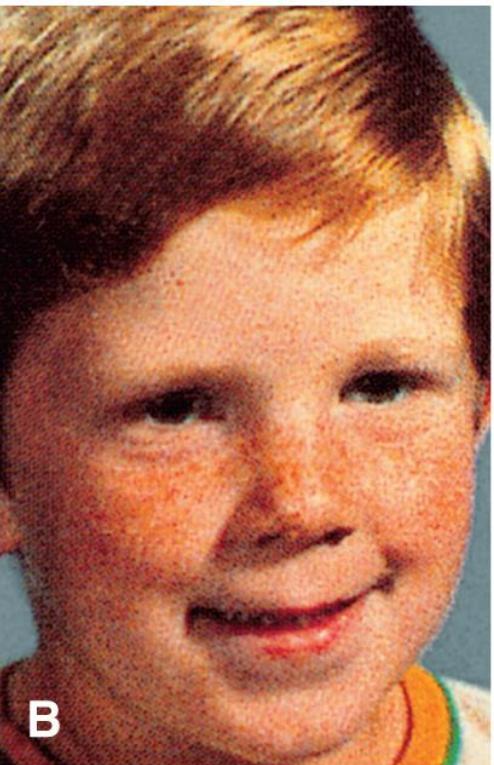

Steroid diabetes – cortisol increases blood glucose

Bone and muscle wasting

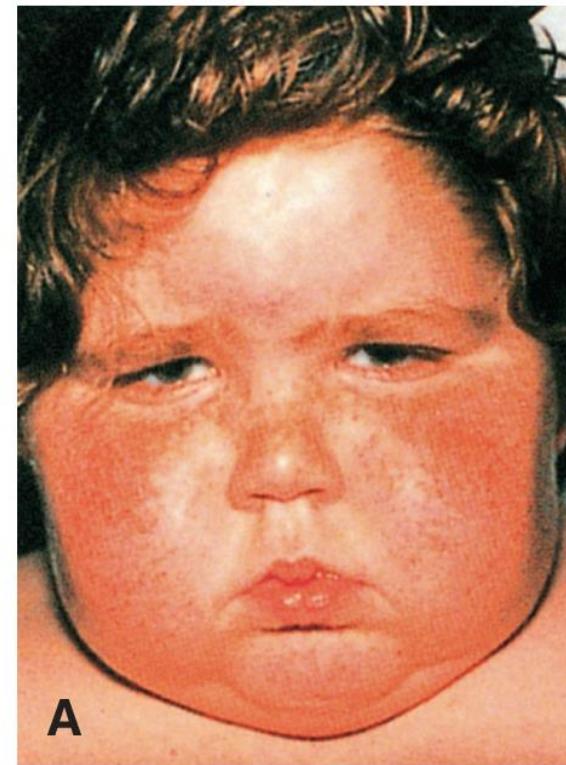

Increased water and Na<sup>+</sup> retention – increased BP, EDEMA

Inability to manage infections

## Cushing's Disease or Syndrome Symptoms

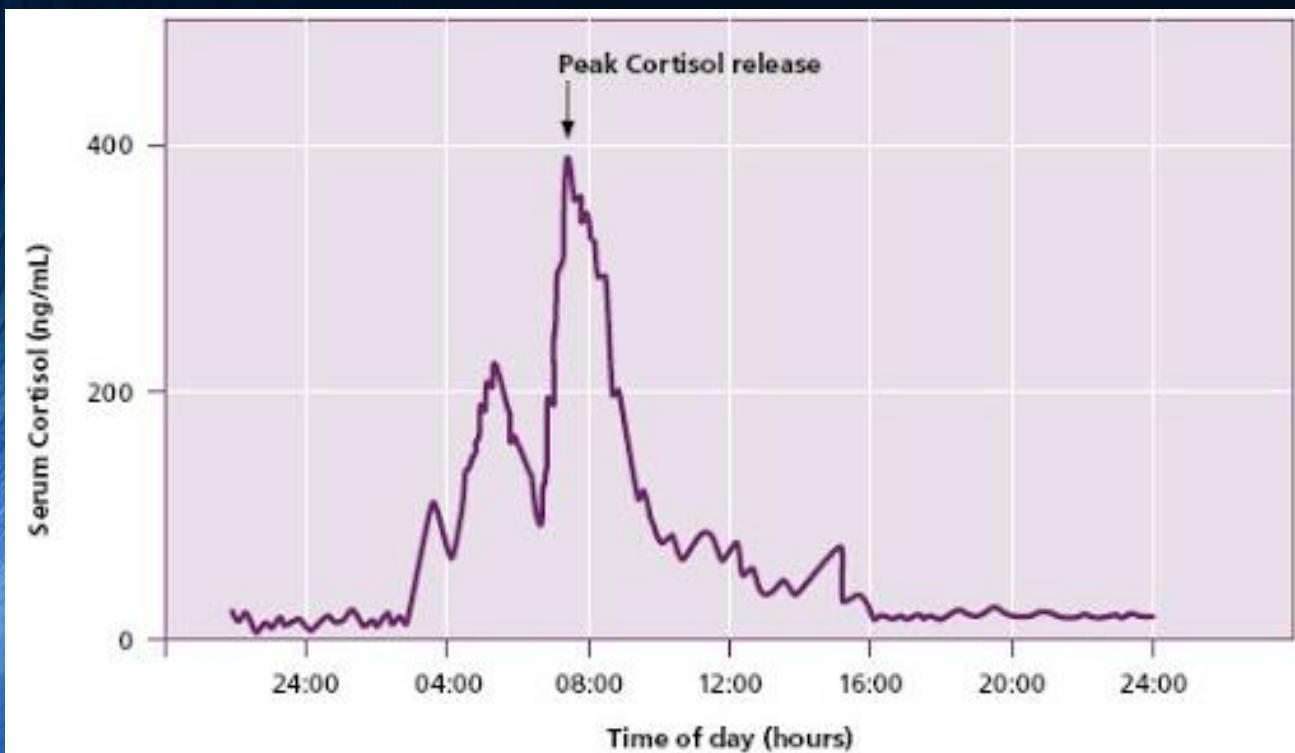

# Hyposecretion of Adrenal Cortex – Addison's Disease

- Affects cortisol and aldosterone production
- Loss of Na+ & H<sub>2</sub>O – dehydration and hypotension (lack of aldosterone)
- Increased ECF K<sup>+</sup> (lack of aldosterone)
- Decreased blood glucose (lack of cortisol)
- Bronzing of the skin
  - ACTH causes increased production of melanin
    - Decreased cortisol leads to increase ACTH
    - ACTH derived from pro opio melanocortin (POMC)
    - Alpha Melanocyte Stimulating Hormone (alpha MSH) derived from POMC
    - Alpha MSH increases melanin production and expression!

Long Loop Feedback

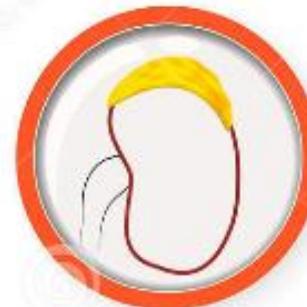

## THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) PATHWAY

### (a) The control of cortisol secretion

# Addison's disease

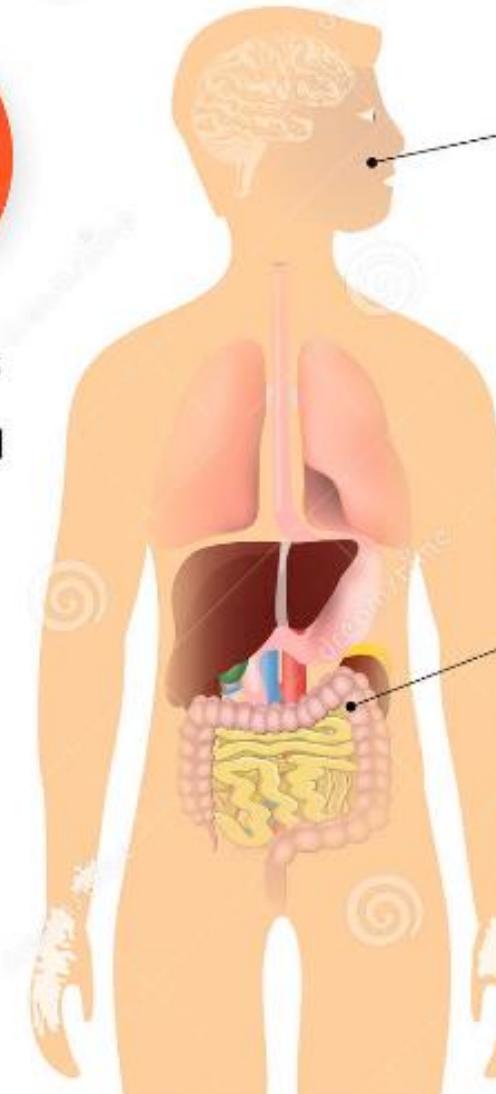

## Addison's disease

**Adrenal glands**  
not produce  
sufficient steroid  
hormones

**Adrenal crisis:**

- fever;
- syncope;
- convulsions;
- hypoglycemia;
- hyponatremia;
- severe vomiting and diarrhea.

**Skin**  
Hyperpigmentation

Low blood pressure  
Weakness  
Weight loss

**Gastrointestinal**  
Nausea  
Diarrhea  
Vomiting  
Constipation  
Abdominal pain

**Skin**  
Vitiligo

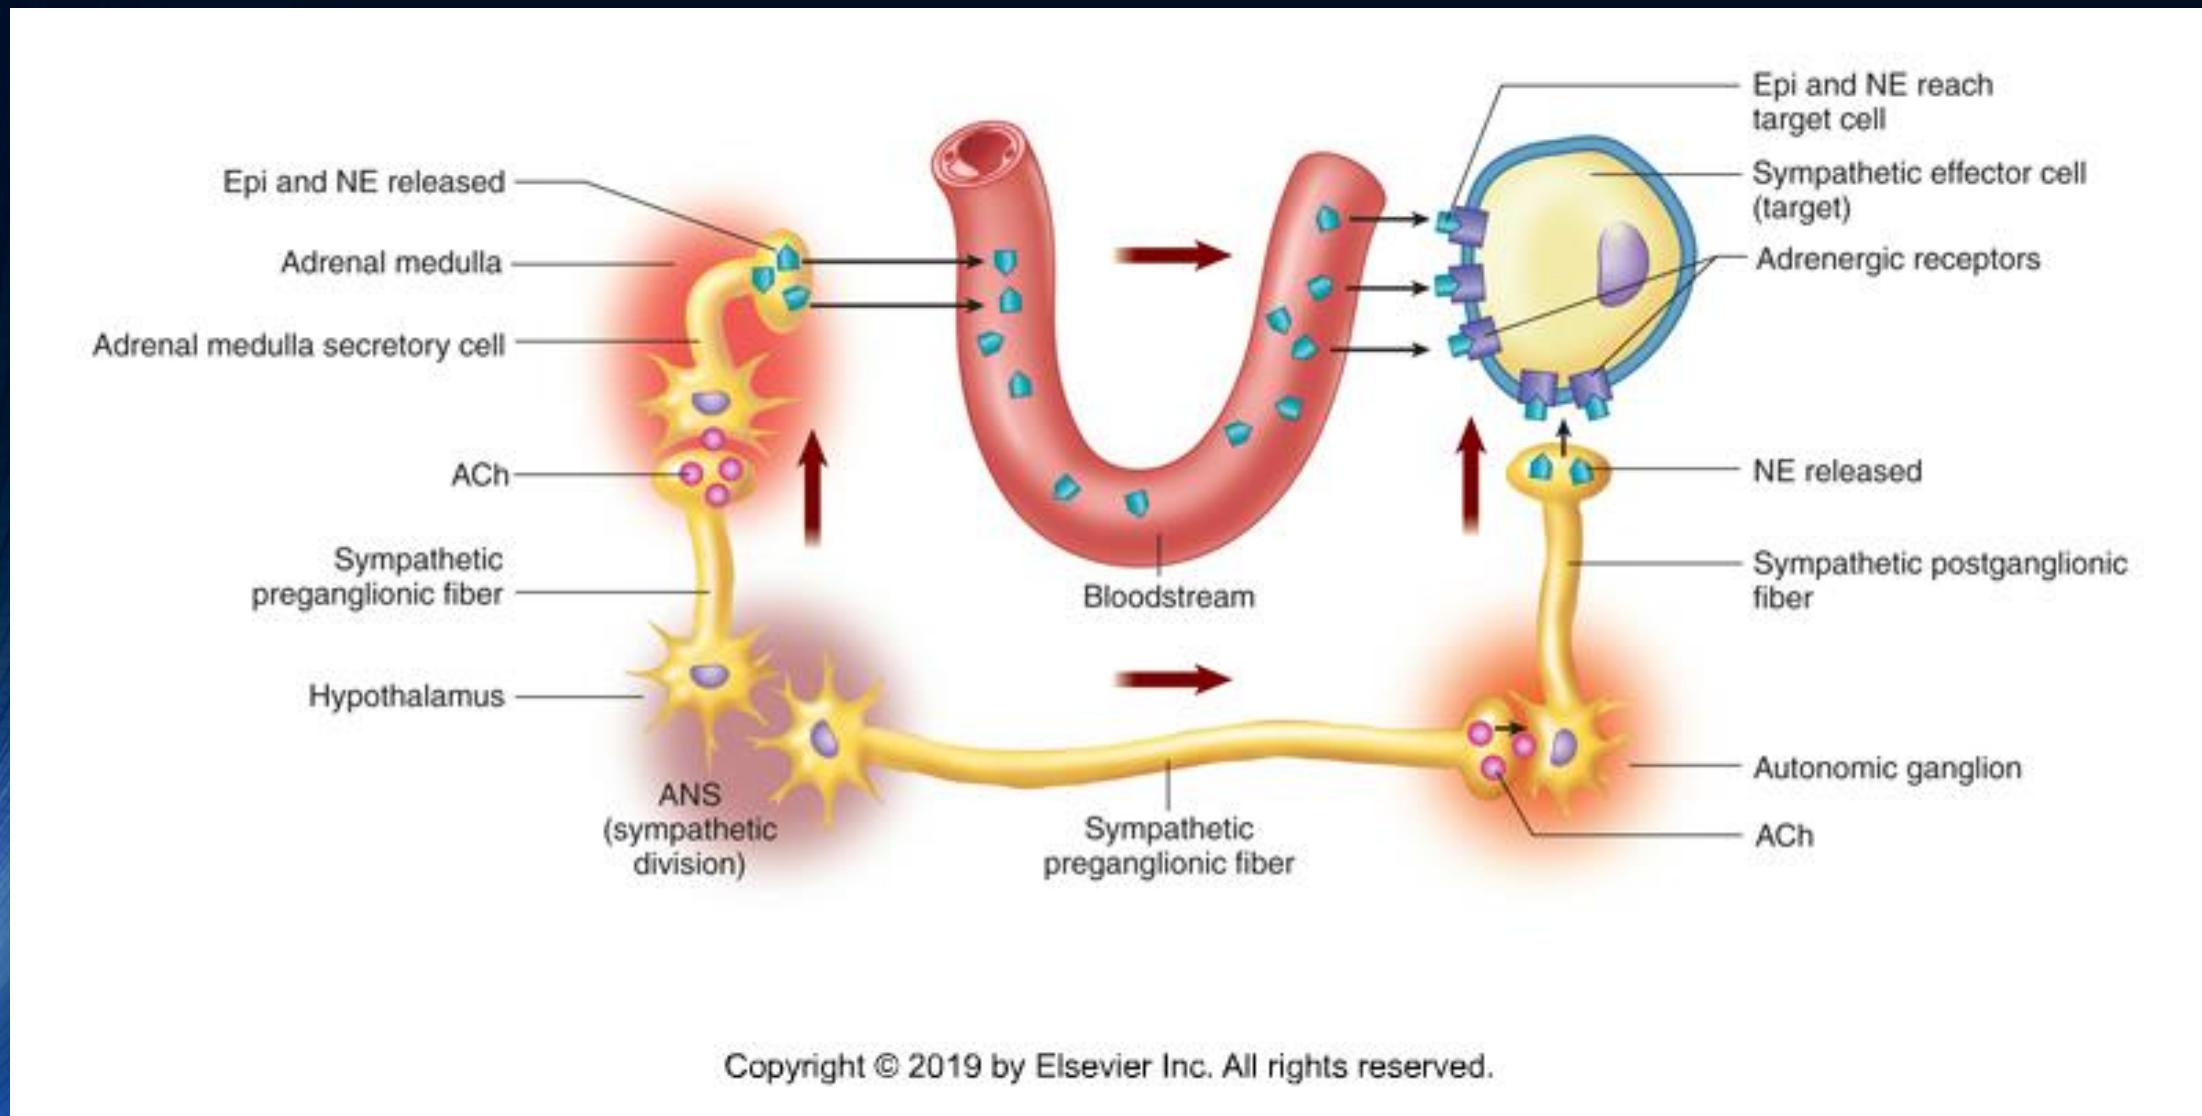

## • Adrenal Medulla

- Modified post-ganglionic sympathetic neurons called medullary chromaffin cells that are surrounded by lots of blood vessels
- Chromaffin cells produce NE (20%) and E (80%) – catecholamines
- Promotes fight / flight responses – same as activation of SNS
- Effects
  - Increase Heart rate & blood pressure
  - Pupils dilate
  - GI tract becomes less active
  - Skeletal muscles become more active
  - Increase Respiratory rate
  - Increase blood glucose
  - Increase CNS alertness
  - Increase sweating

# General Adaptation Syndrome

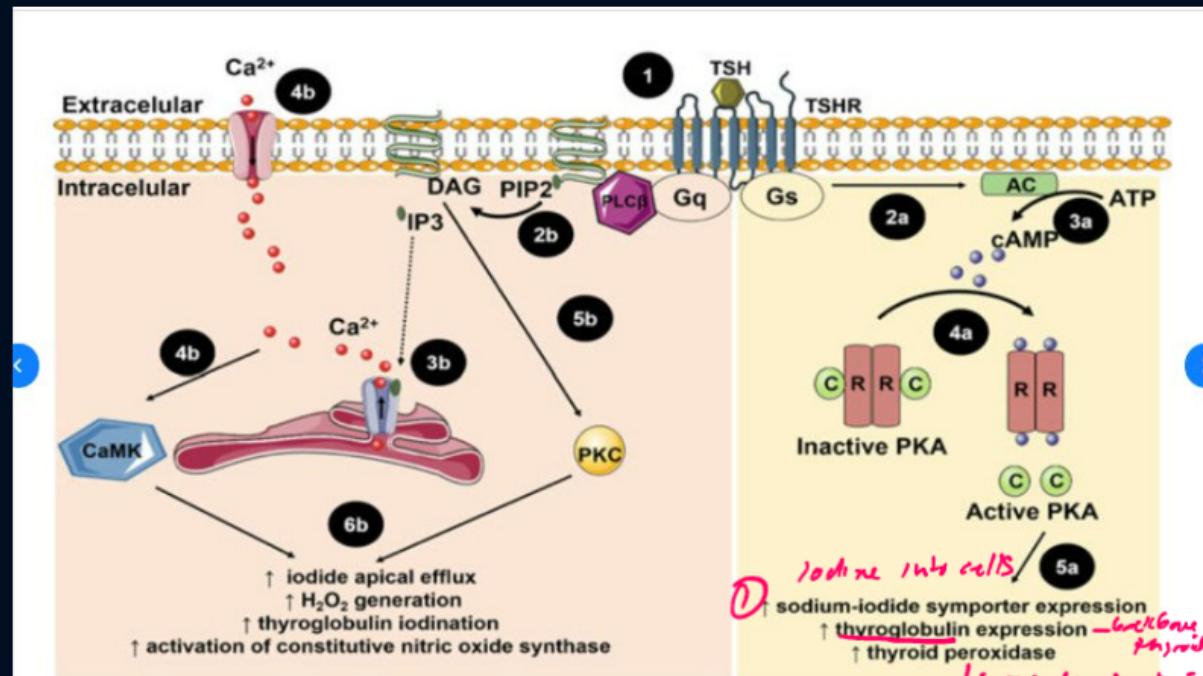

- Stressor – real or perceived threat to well-being
- Three stage process
  - Alarm – stress increases activity of parts of the hypothalamus
    - Increased secretion of cortisol, increased activation of sympathetic nervous system (fight or flight response)
  - Resistance – maintenance of alarm stage, forming a new set point for homeostasis
    - Body attempts to compensate
    - If stressor is managed, homeostasis returns to normal set points
    - If stressor is not managed, alarm stage will continue – will eventually be counter-productive
  - Exhaustion – body's resources have been depleted
    - Increased risk of becoming sick

# Stress response – GAS

**RELEVANT**

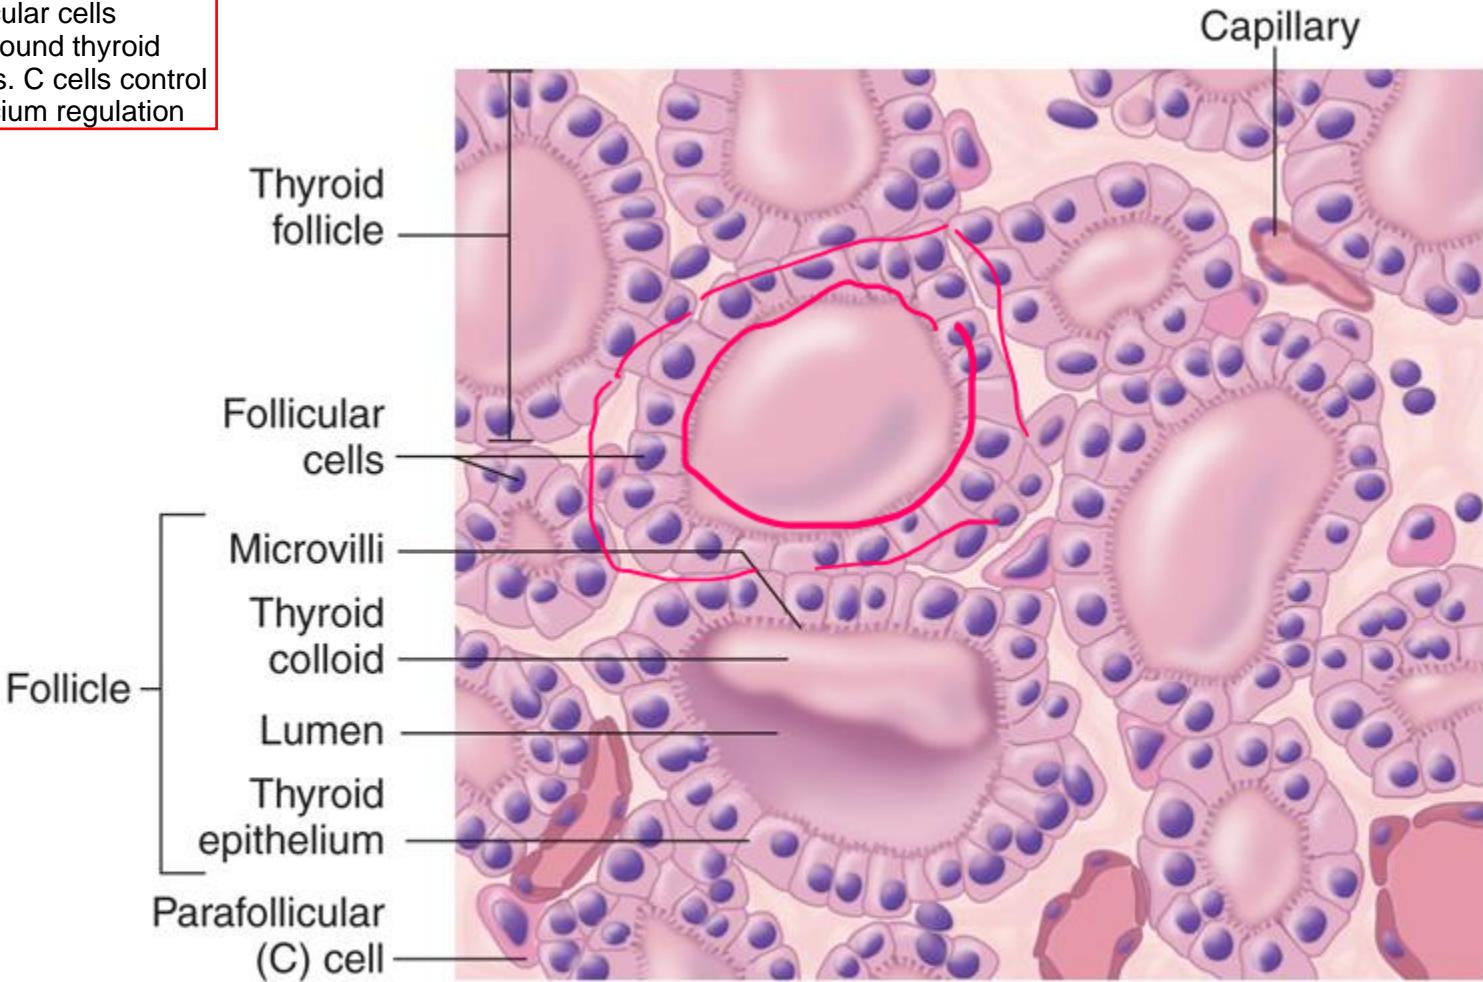

- TSH binds to TSH-R on basolateral aspect of thyroid follicular cell
- TSH-R – G-protein coupled receptor, activates adenylyl cyclase and cAMP. Increases protein kinase A (PKA)
- PKA has number of effects

2 Signaling pathways activated by thyroid stimulating hormone (TSH) in thyroid follicular cells. (1) TSH binds to the thyroid stimulating hormone receptor (TSHR), activating two Gα protein subtypes: Gs and Gq. These proteins activate two different regulatory pathways: cAMP and phospholipase-C (PLC) pathways, respectively. cAMP pathway: (2a) Gs activates adenylate cyclase (AC); (3a) AC converts adenosine triphosphate (ATP) to cAMP; (4a) cAMP binds to the regulatory subunits (R) of protein kinase A (PKA), releasing and activating the catalytic subunits (C) of this protein (5a). Activated PKA activates transcription of genes involved in the thyroid hormone production: sodium-iodide symporter, thyroglobulin and thyroid peroxidase. PLC pathway: (2b) Gq activation stimulates PLC that hydrolyzes phosphatidylinositol 4,5-bisphosphate (PIP2) into diacylglycerol (DAG) and inositol 1,4,5-triphosphate (IP3); (3b) IP3 binds to its endoplasmic reticulum receptors releasing the Ca<sup>2+</sup> stored in this organelle; (4b) Increased intracellular Ca<sup>2+</sup> is followed by an increase of Ca<sup>2+</sup> from the extracellular medium and calmodulin-dependent protein kinases (CaMK) activation; (5b) DAG activates the protein kinase C (PKC); (6b) PLC pathway, through CaMK and PKC activation, regulate the iodide apical efflux, H<sub>2</sub>O<sub>2</sub> generation, thyroglobulin iodination and constitutive activation of nitric oxide synthase. Notes Dotted arrows depict particles movement

# Thyroid Gland Tissue Level

follicular cells surround thyroid cells. C cells control calcium regulation

A

iodine required to make thyroid hormones, so intake increased. Thyroglobulin made more as backbone. Thyroid peroxidase also increased to combine the iodine and thyroglobulin. C

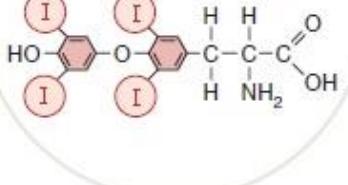

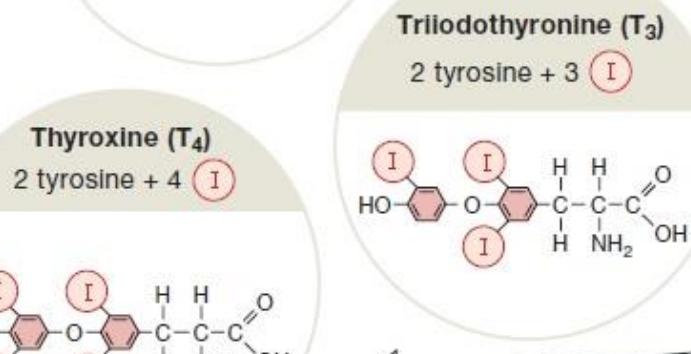

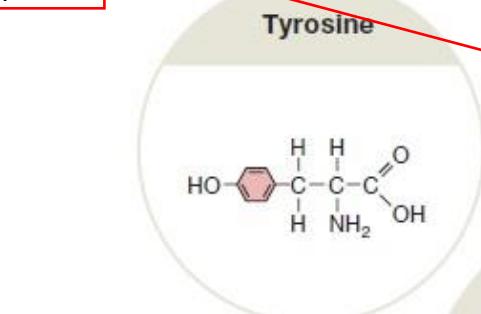

TSH increases sodium iodine transporters

# T<sub>3</sub> T<sub>4</sub> Synthesis

follicular cells assemble components, colloid cells combine components into thyroid hormones

Thyroid hormones move back out of follicular cells into blood stream

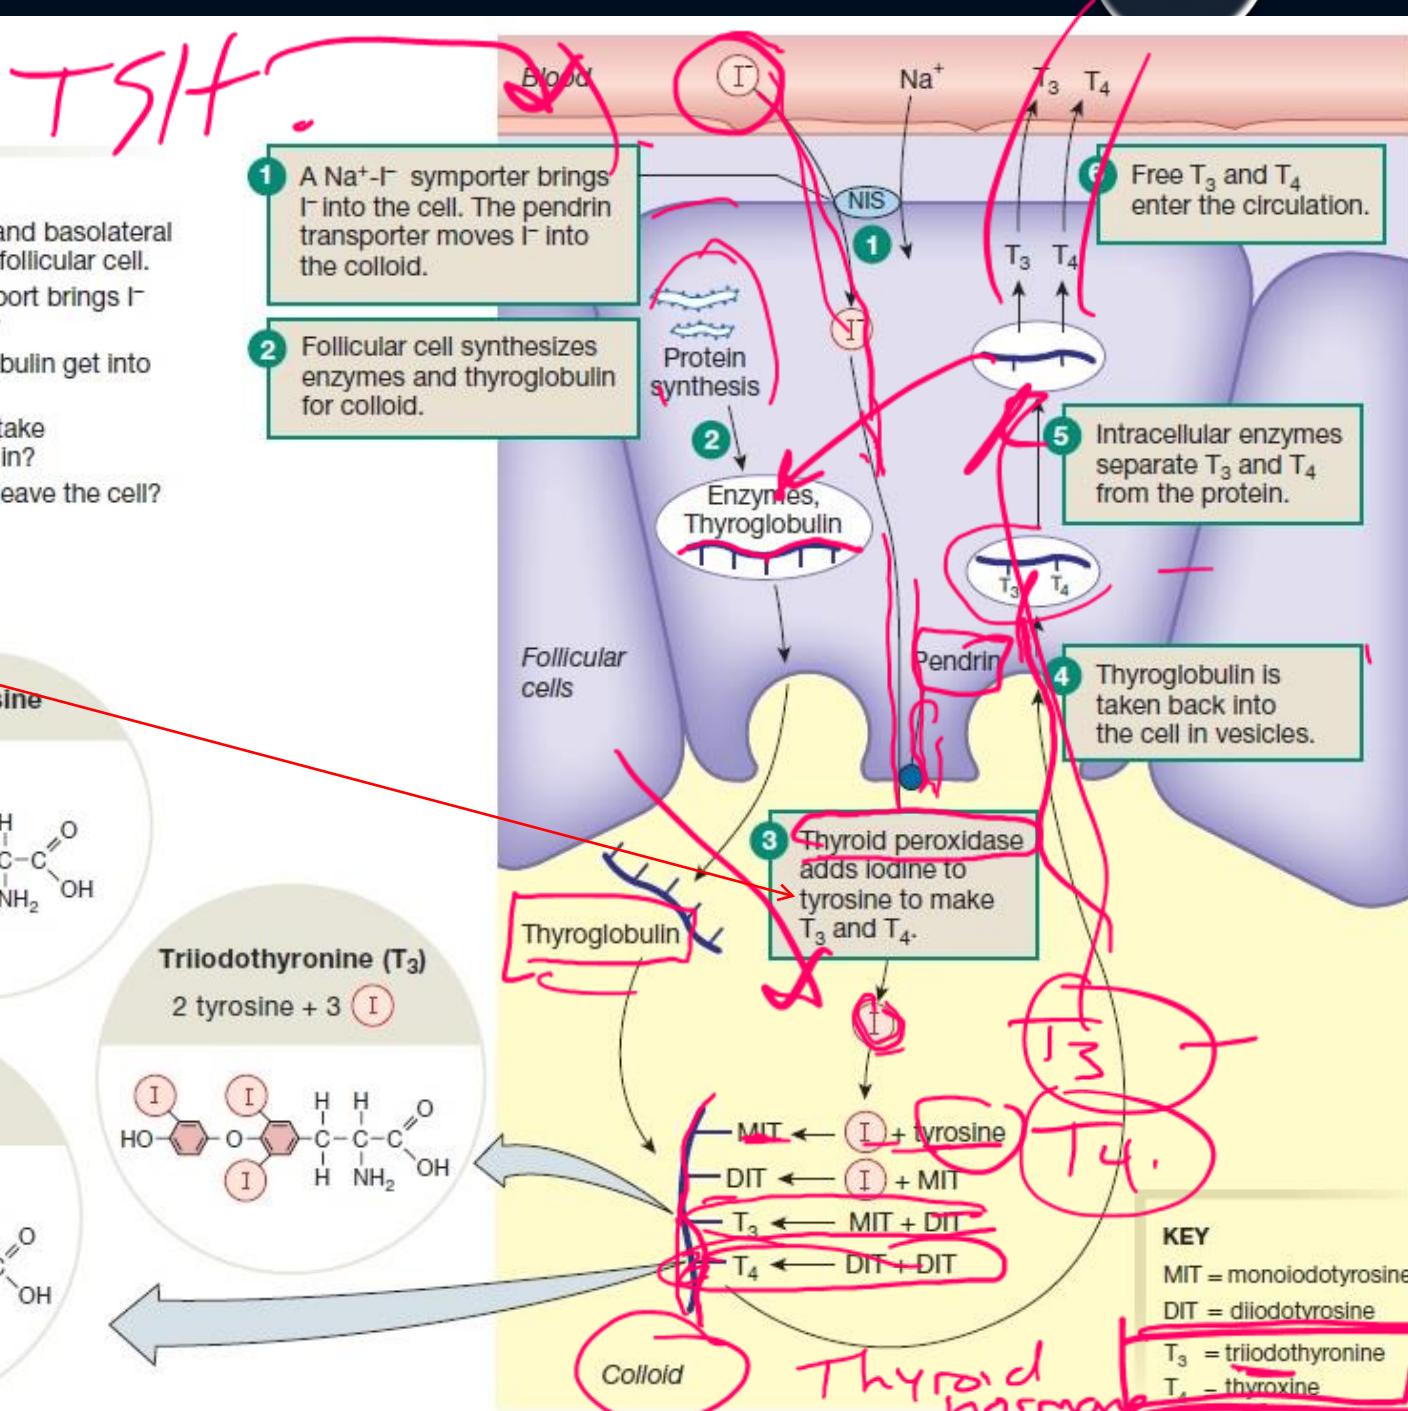

Tyrosine are the units making up a thyroglobulin

RELEVANT.  
ALSO KNOW HOW  
TSH works from  
what i pasted 2  
slides ago

## FIGURE QUESTIONS

- Identify the apical and basolateral membranes of the follicular cell.
- What kind of transport brings I<sup>-</sup> into follicular cells?
- How does thyroglobulin get into the colloid?
- How does the cell take thyroglobulin back in?
- How do T<sub>3</sub> and T<sub>4</sub> leave the cell?

T4 is more abundant, acts as storage molecules. T3 is more active.

# Transportation and Activation of T<sub>3</sub> & T<sub>4</sub>

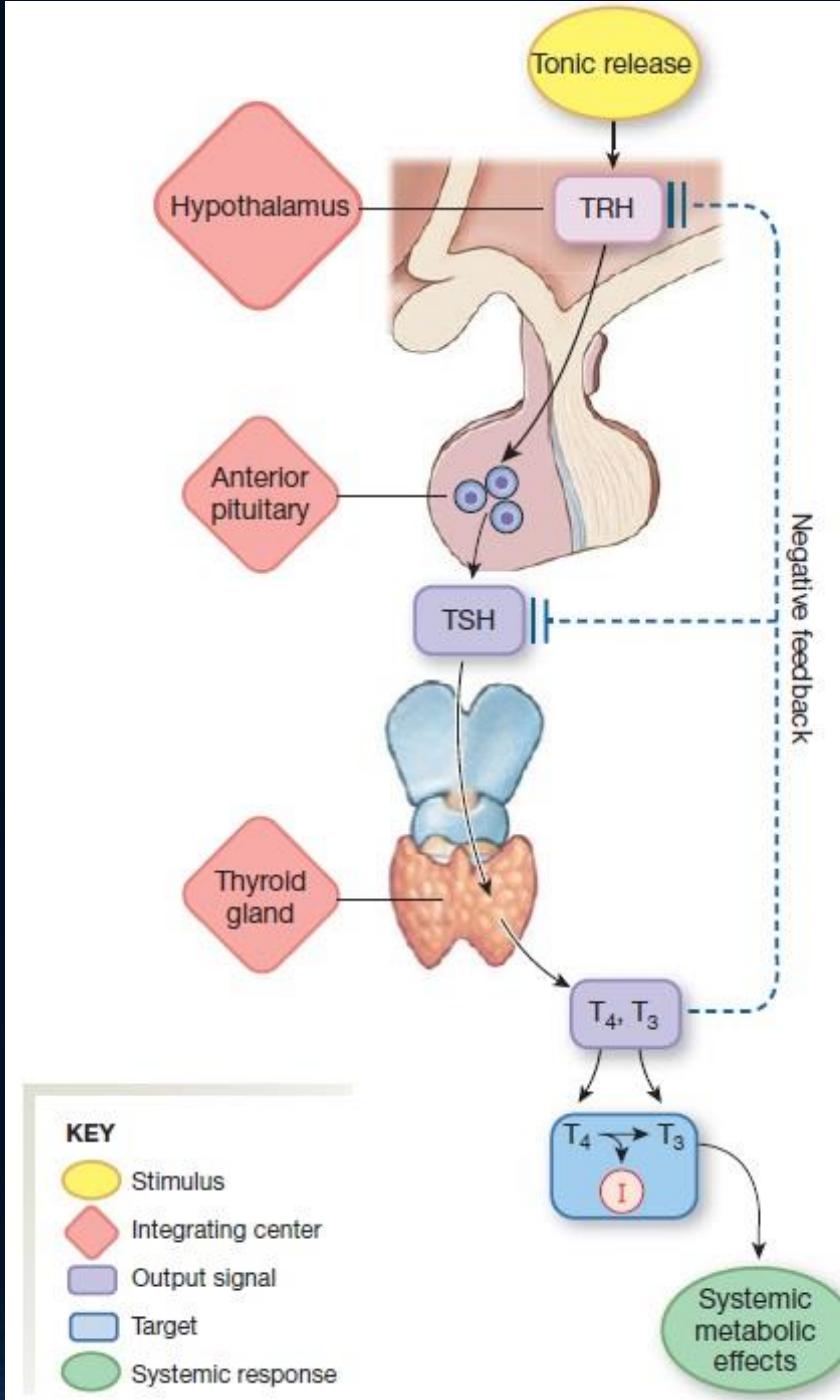

- Thyroxine binding globulin carries T<sub>3</sub> and T<sub>4</sub> in blood – specific binding
- Serum Albumen Carries T<sub>3</sub> and T<sub>4</sub> – Low affinity but high capacity
- At tissue, T<sub>4</sub> is converted to T<sub>3</sub> (more biologically active than t<sub>4</sub>) by deiodinase
- Starvation response – reduction in deiodinase activity except in brain, heart, skeletal muscle and thyroid. Why?

Thyroid hormones control metabolism. Too much speeds everything up (high bp, high temp), too little slows things down (bradycardia, hypothermic)

## Effects of T<sub>3</sub> & T<sub>4</sub>

- Increase basal metabolic rate (BMR; consumption of O<sub>2</sub> and energy to meet minimum requirements to survive)
- Increases protein synthesis and protein degradation
- Increases rate of glycogenolysis and gluconeogenesis
- Increases lipolysis
- Increases HR, FoC and cardiac output
- In neonate, essential for normal neurologic development (particularly myelin, axon development and neurotransmitters)

# Regulation of Secretion of T<sub>3</sub> & T<sub>4</sub>

Thyroid Hormones	
Cell of origin	Thyroid follicle cells
Chemical nature	Iodinated amine
Biosynthesis	From iodine and tyrosine. Formed and stored on thyroglobulin in follicle colloid.
Transport in the circulation	Bound to thyroxine-binding globulin and albumins
Half-life	6-7 days for thyroxine (T <sub>4</sub> ); about 1 day for triiodothyronine (T <sub>3</sub> )
Factors affecting release	Tonic release
Control pathway	TRH (hypothalamus) → TSH (anterior pituitary) → T <sub>3</sub> + T <sub>4</sub> (thyroid) → T <sub>4</sub> deiodinates in tissues to form more T <sub>3</sub>
Target cells or tissues	Most cells of the body
Target receptor	Nuclear receptor
Whole body or tissue reaction	↑ Oxygen consumption (thermogenesis). Protein catabolism in adults but anabolism in children. Normal development of nervous system
Action at cellular level	Increases activity of metabolic enzymes and Na <sup>+</sup> -K <sup>+</sup> -ATPase
Action at molecular level	Production of new enzymes
Feedback regulation	T <sub>3</sub> has negative feedback on anterior pituitary and hypothalamus.

goiter

- Causes
  - lack of Iodine (primary hypothyroidism)
  - lack of response to TSH

- S&S

- Weight gain
- Cold intolerance
- Slow HR, low cardiac output
- Fatigue
- Cool extremities
- Dry skin
- Flat, lack of energy
- constipation

- Treatment – exogenous T<sub>4</sub> (levothyroxine)

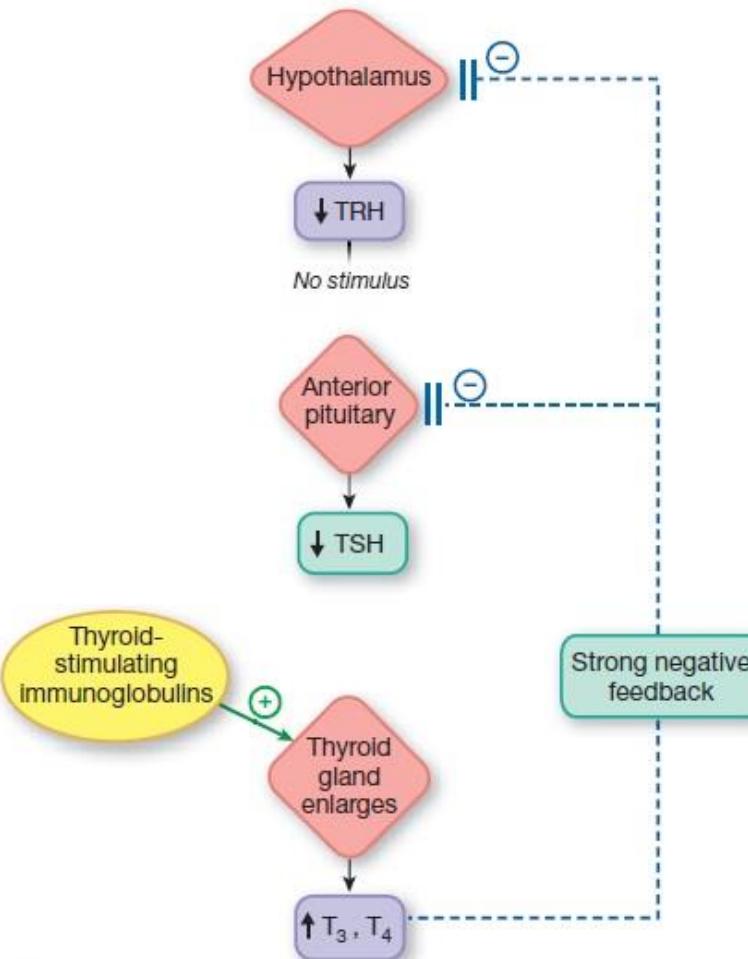

# Hypothyroidism

# Hypothyroidism – Feedback

## THYROID PATHOLOGIES

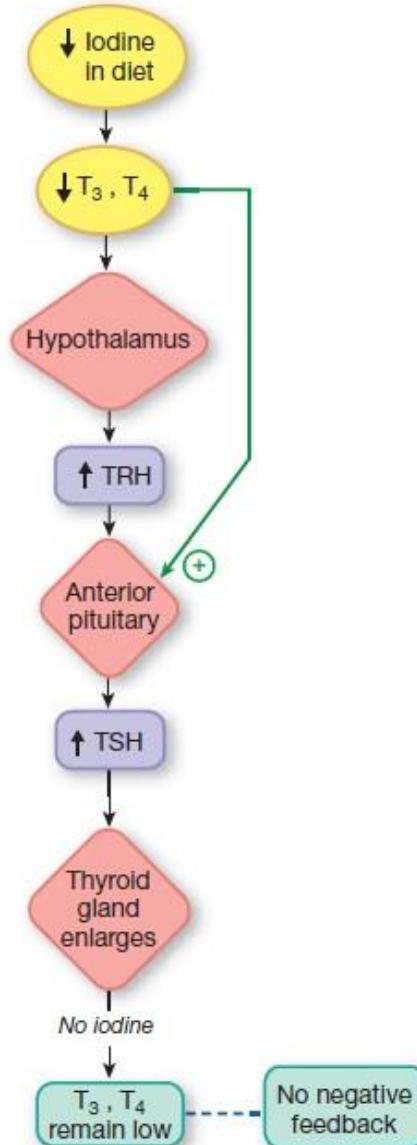

(a) Hyperthyroidism due to Graves' disease. In Graves' disease, thyroid-stimulating immune proteins (TSI) bind to thyroid gland TSH receptors and cause the gland to hypertrophy.

### FIGURE QUESTION

Draw the pathway for a person with a pituitary tumor that is oversecreting TSH. Would this person be hypothyroid or hyperthyroid? Would this person have a goiter?

(b) Hypothyroidism due to low iodine. In hypothyroidism caused by iodine deficiency, absence of negative feedback increases TSH secretion and results in goiter.

- Causes
  - Graves disease (autoimmune stim of TSH receptor)
  - Thyroid tumour
- S&S
  - Weight loss, high blood sugar
  - heat intolerance
  - Fast HR, High cardiac output
  - "Spun" / irritable
  - Cool extremities
  - thin skin (little subcutaneous fat)
  - Exophthalmos
  - Hypermotility of GI tract
- Treatment – depends on the cause;  
antithyroids, beta blockers, radioactive iodine

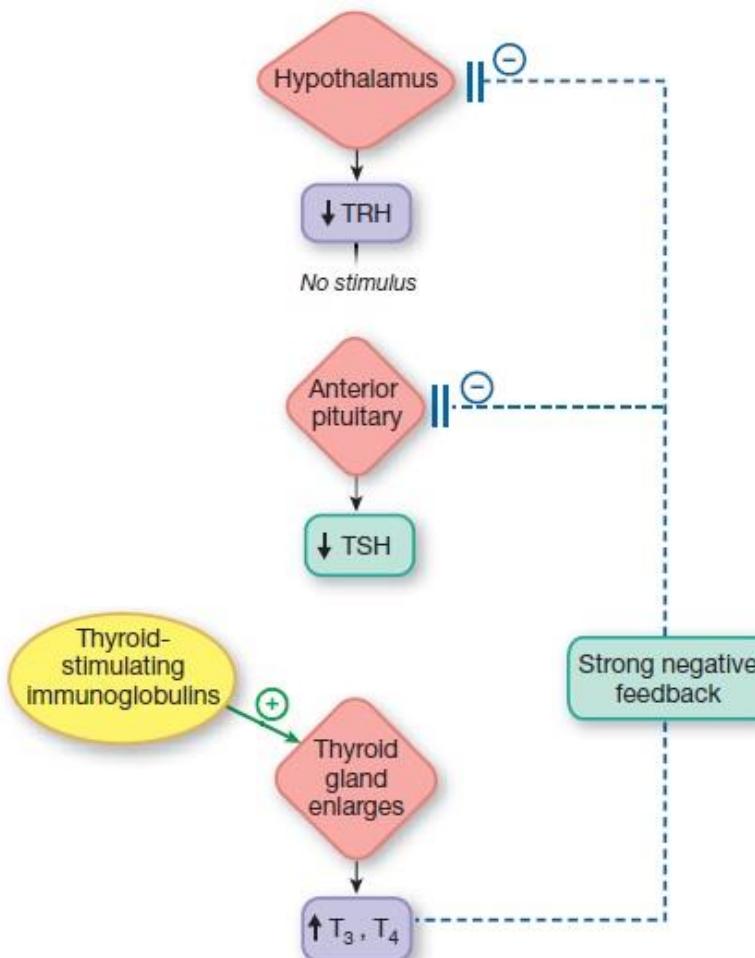

# Hyperthyroidism

# Hypothyroidism – Feedback

## THYROID PATHOLOGIES

(b) **Hypothyroidism due to low iodine.** In hypothyroidism caused by iodine deficiency, absence of negative feedback increases TSH secretion and results in goiter.

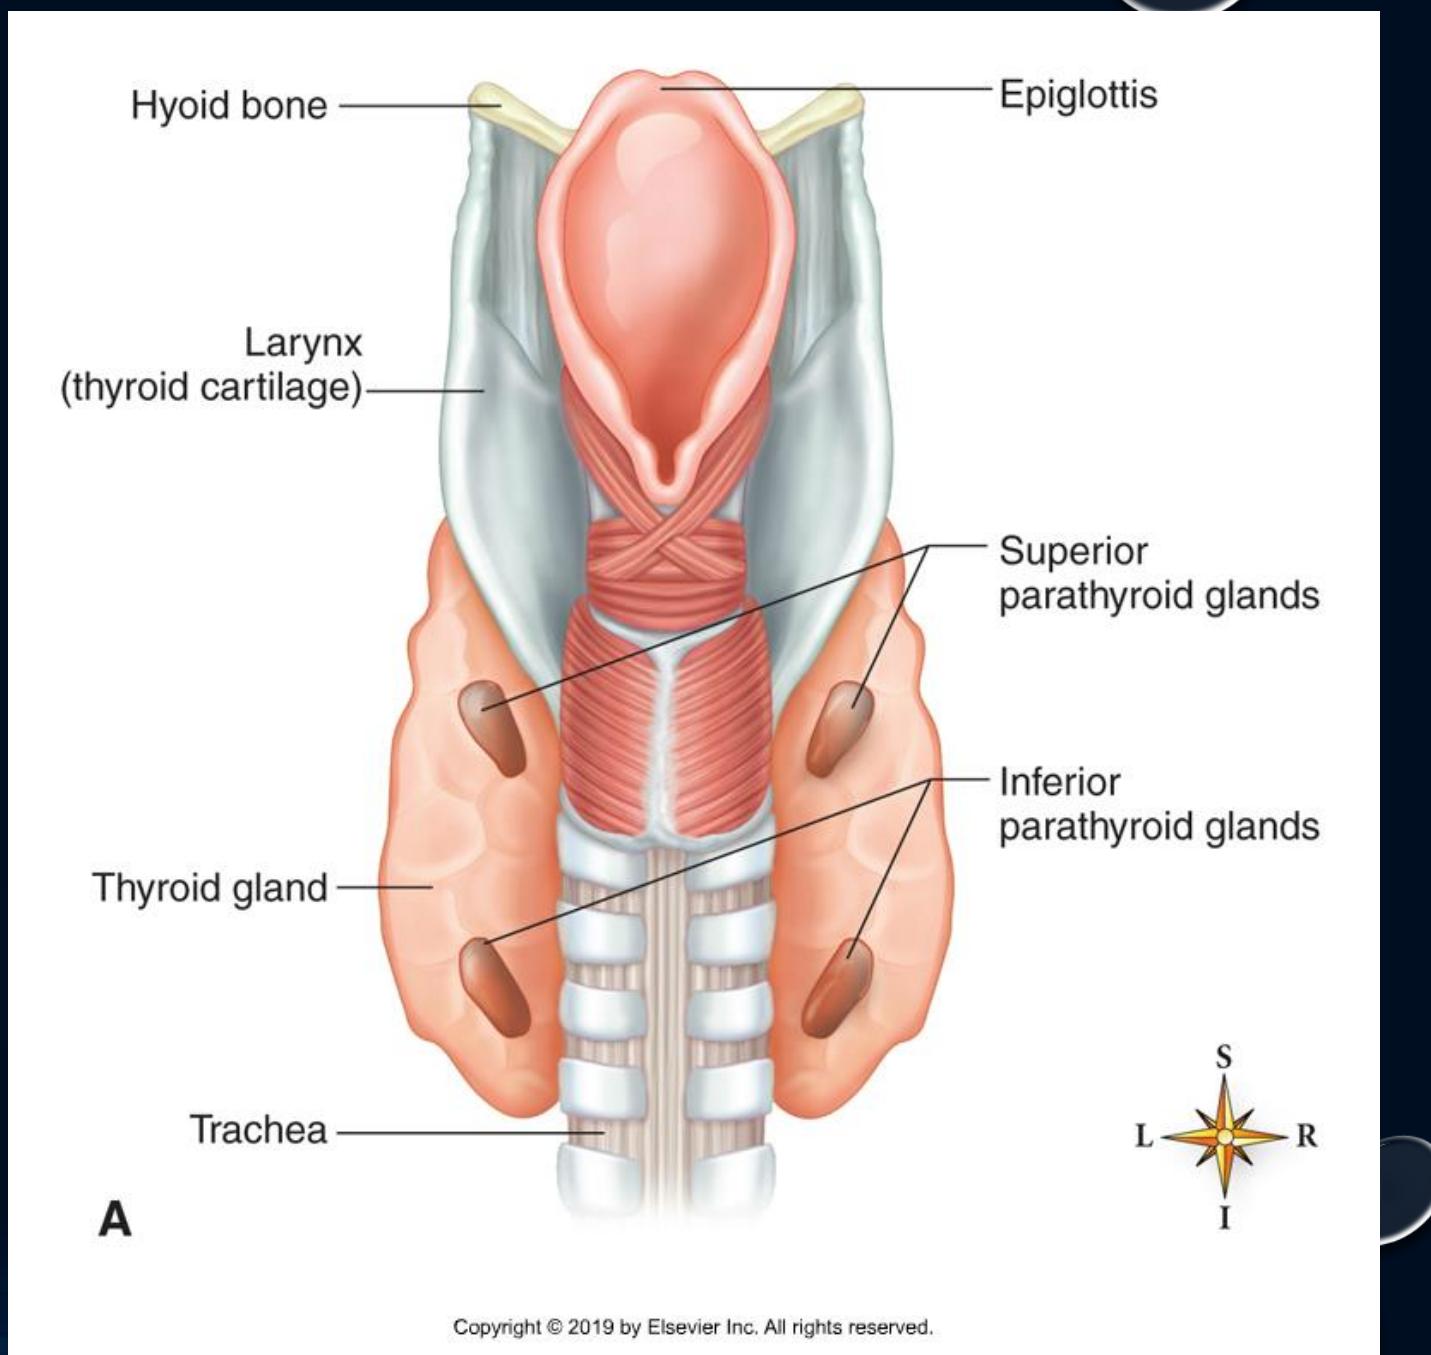

# Calcium Regulation

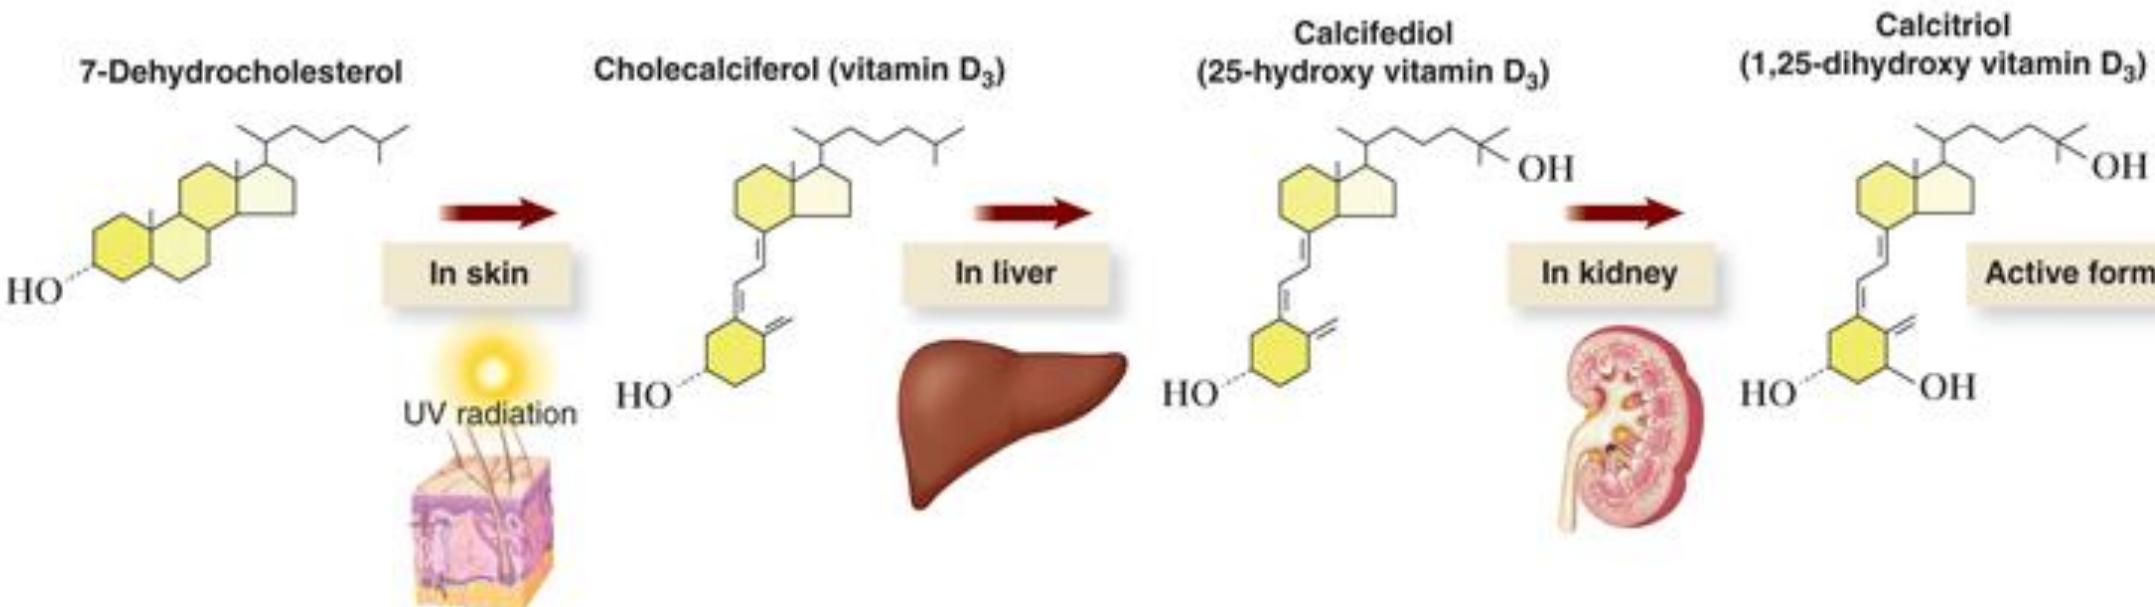

- Parathyroid hormone
  - Raise ECF  $\text{Ca}^{2+}$  by increasing Bone resorption,  $\text{Ca}^{2+}$  absorption &  $\text{Ca}^{2+}$  reabsorption
- Vitamin D
  - Active form increases  $\text{Ca}^{2+}$  absorption, raising ECF  $\text{Ca}^{2+}$
- Calcitonin
  - Decreases ECF  $\text{Ca}^{2+}$  by increasing bone matrix deposition

# Parathyroid Glands

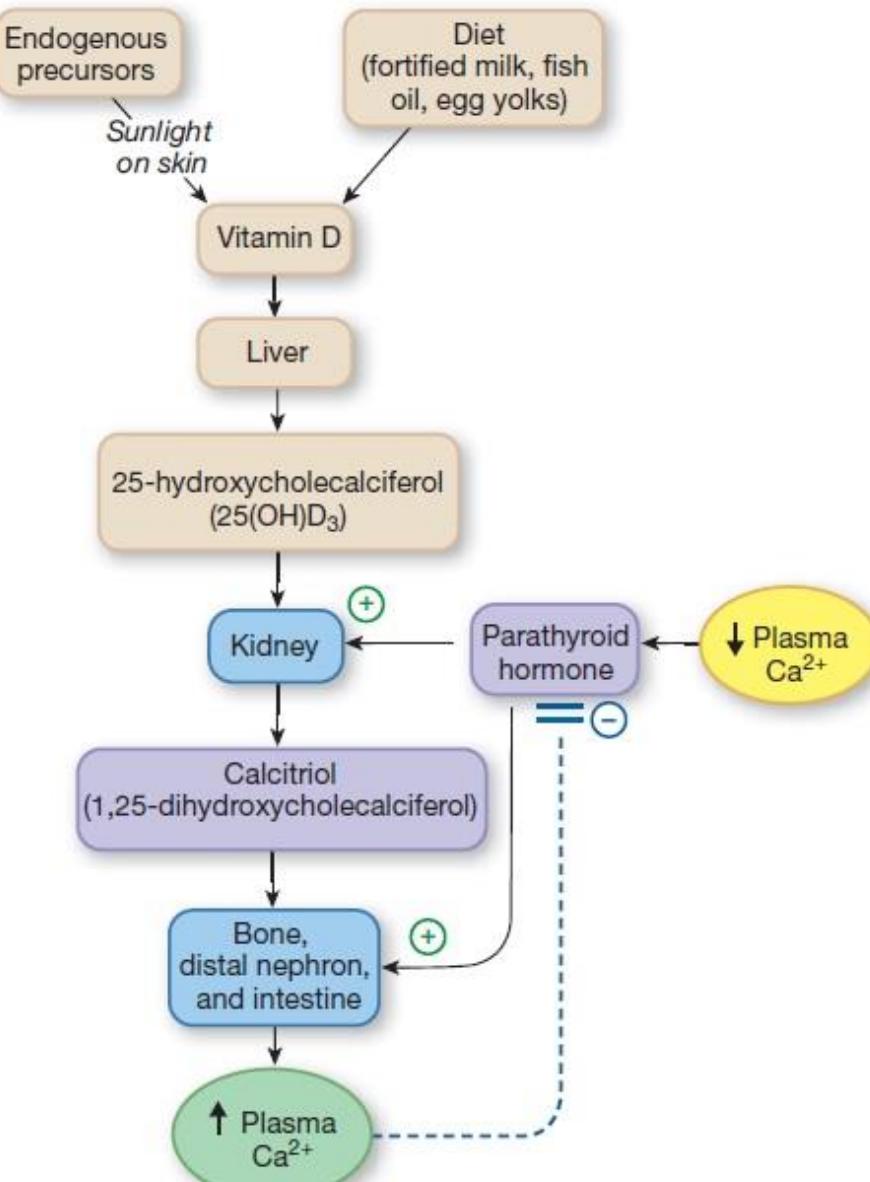

# Vitamin D Metabolism

## ENDOCRINE CONTROL OF CALCIUM BALANCE

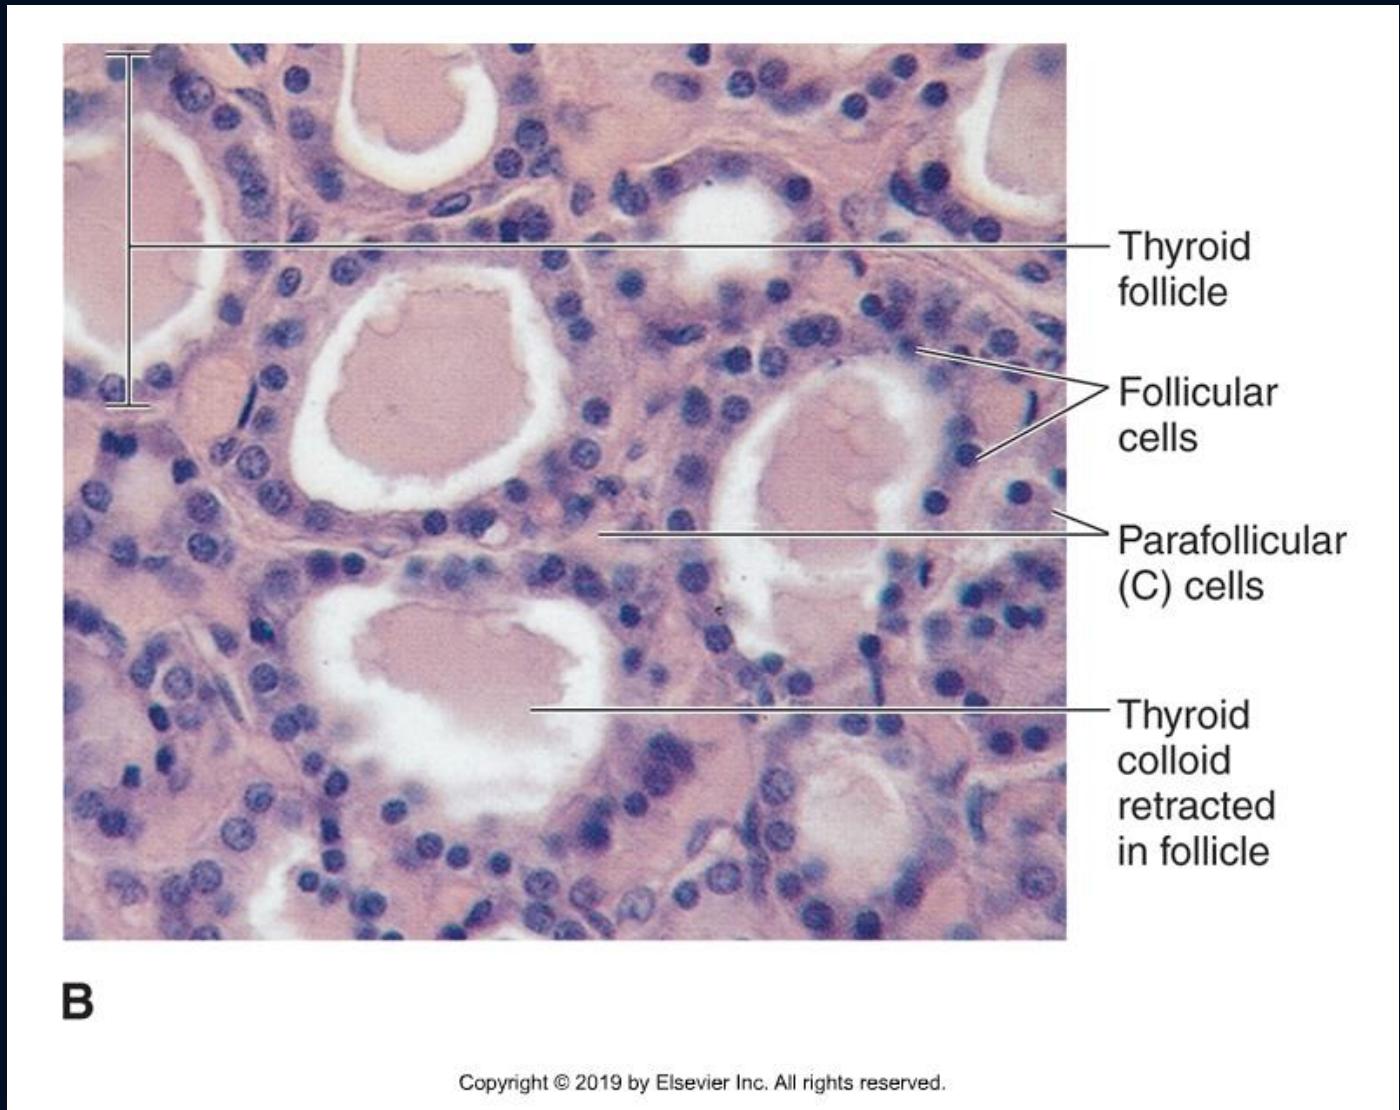

PTH works with calcitriol to promote bone resorption, intestinal  $\text{Ca}^{2+}$  absorption, and distal nephron  $\text{Ca}^{2+}$  reabsorption, all of which tend to elevate plasma  $\text{Ca}^{2+}$  concentrations.

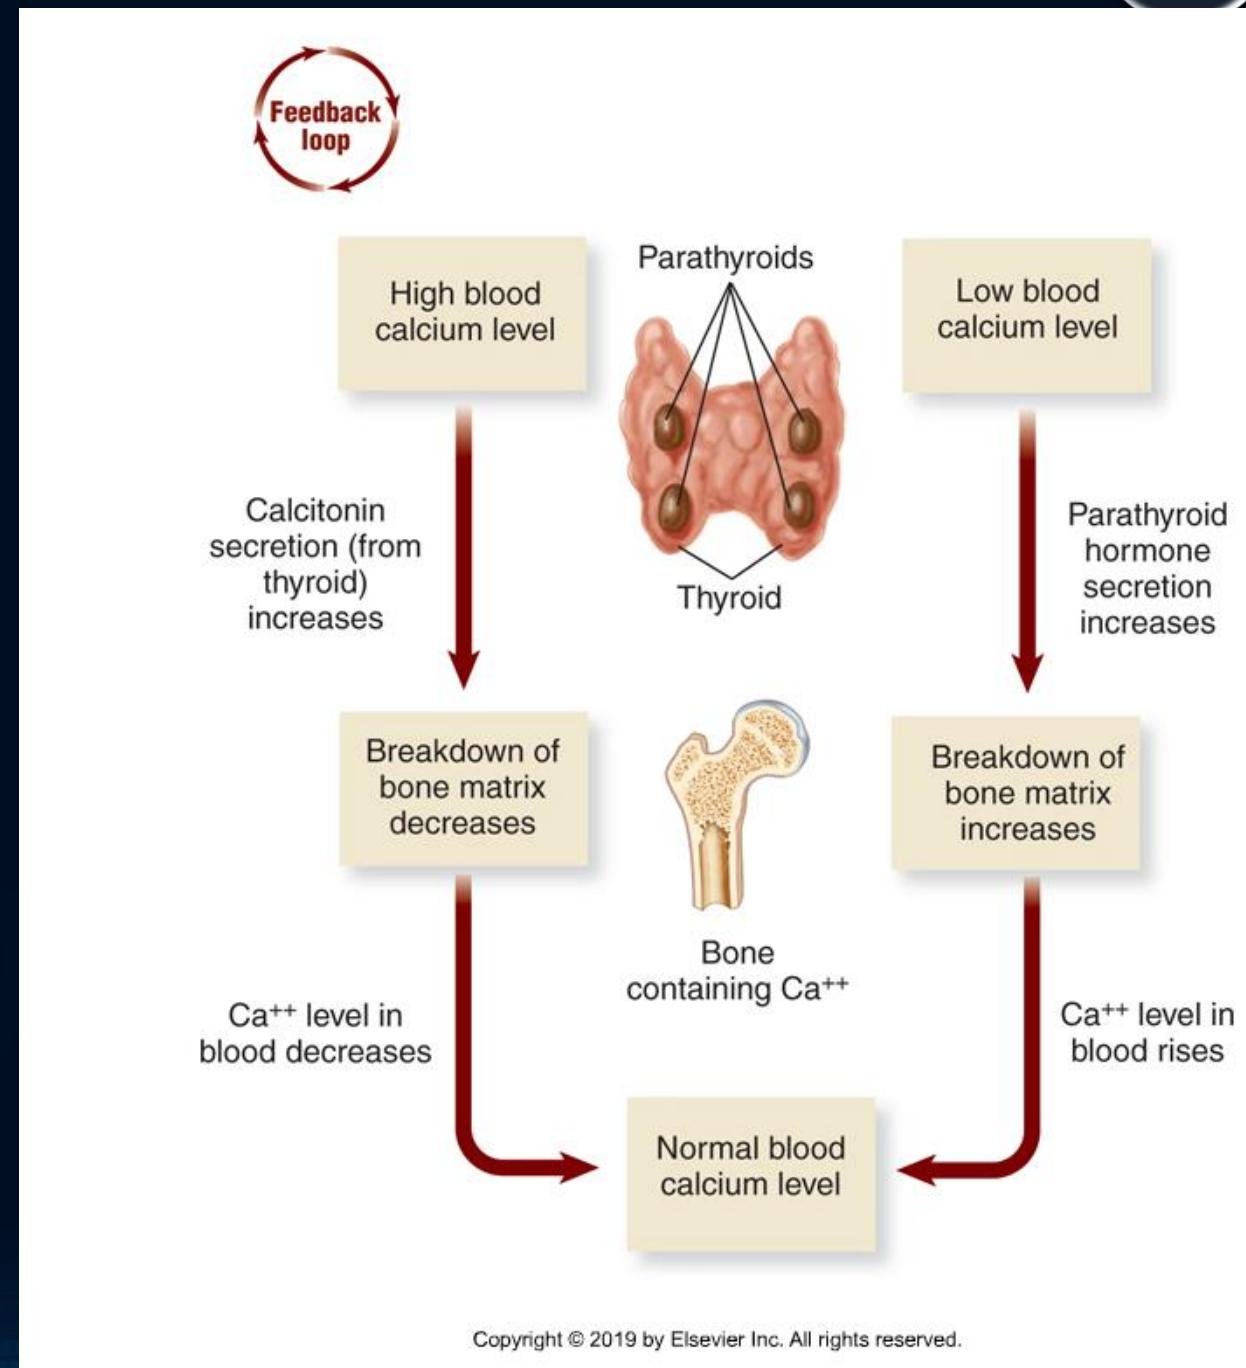

### VITAMIN D<sub>3</sub> (CALCITRIOL, 1,25-DIHYDROXYCHOLECALCIFEROL)

Origin	Complex biosynthesis; see below
Chemical nature	Steroid
Biosynthesis	Vitamin D formed by sunlight on precursor molecules or ingested in food; converted in two steps (liver and kidney) to 1,25(OH) <sub>2</sub> D <sub>3</sub>
Transport in the circulation	Bound to plasma protein
Stimulus for synthesis	↓ $\text{Ca}^{2+}$ . Indirectly via PTH. Prolactin also stimulates synthesis.
Target cells or tissues	Intestine, bone, and kidney
Target receptor	Nuclear
Whole body or tissue reaction	↑ Plasma $\text{Ca}^{2+}$
Action at molecular level	Stimulates production of calbindin, a $\text{Ca}^{2+}$ -binding protein, and of CaSR in parathyroid gland. Associated with intestinal transport by unknown mechanism
Feedback regulation	↑ Plasma $\text{Ca}^{2+}$ shuts off PTH secretion

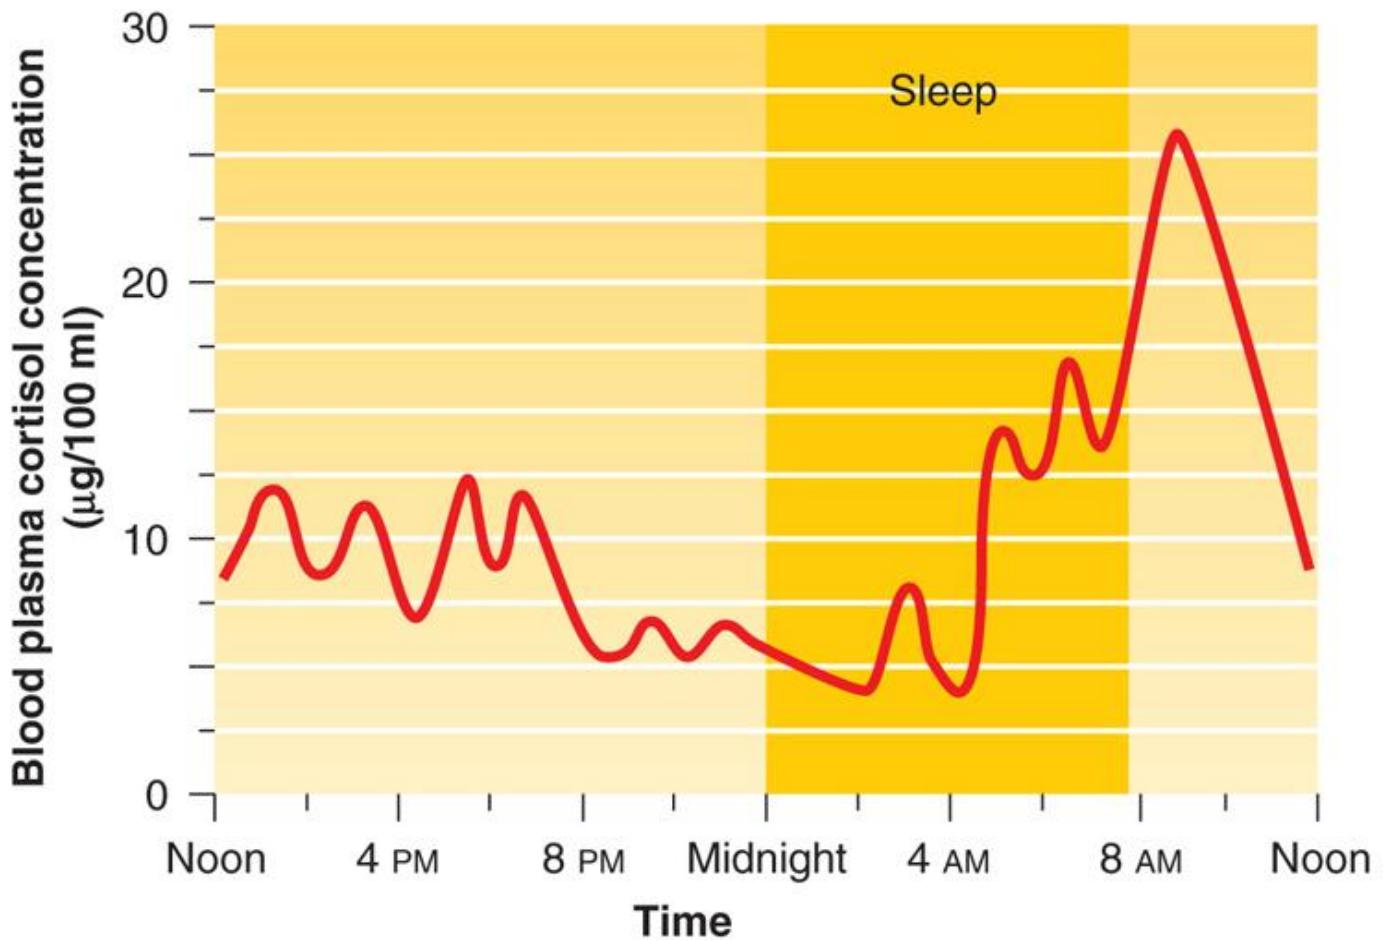

# Calcitonin

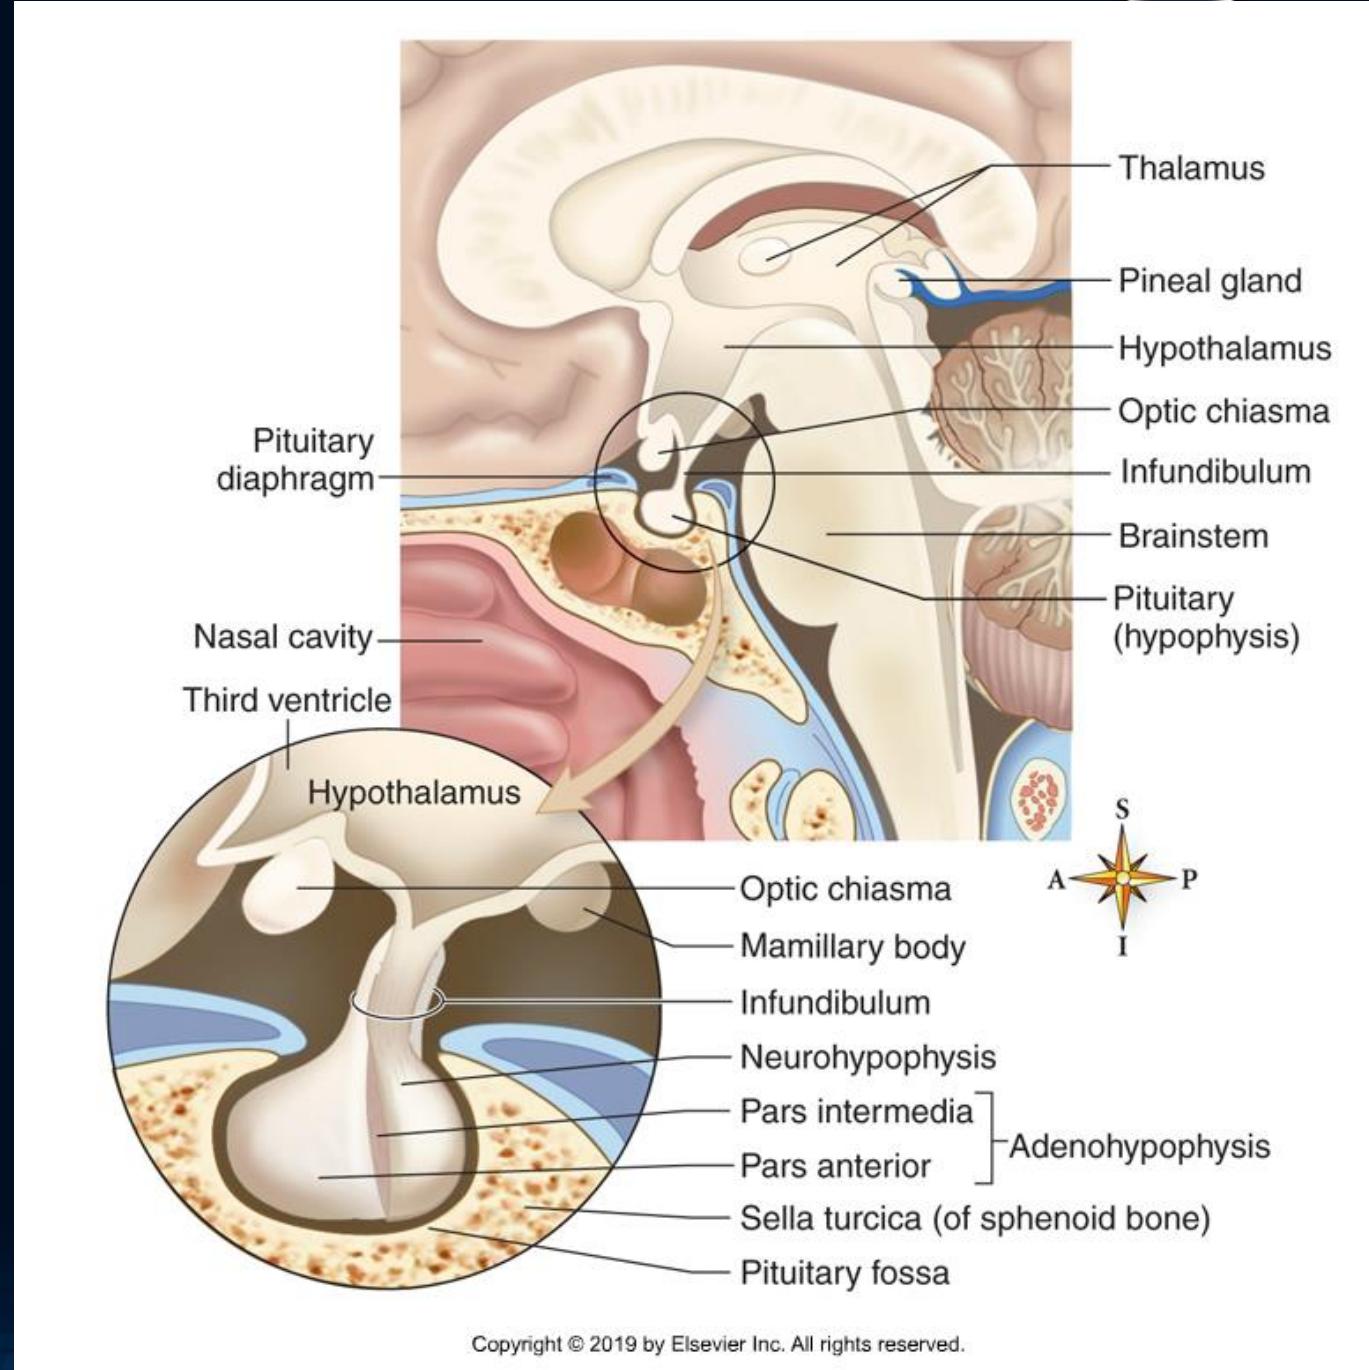

# Calcitonin – role in $\text{Ca}^{++}$ regulation

# Circadian Rhythms

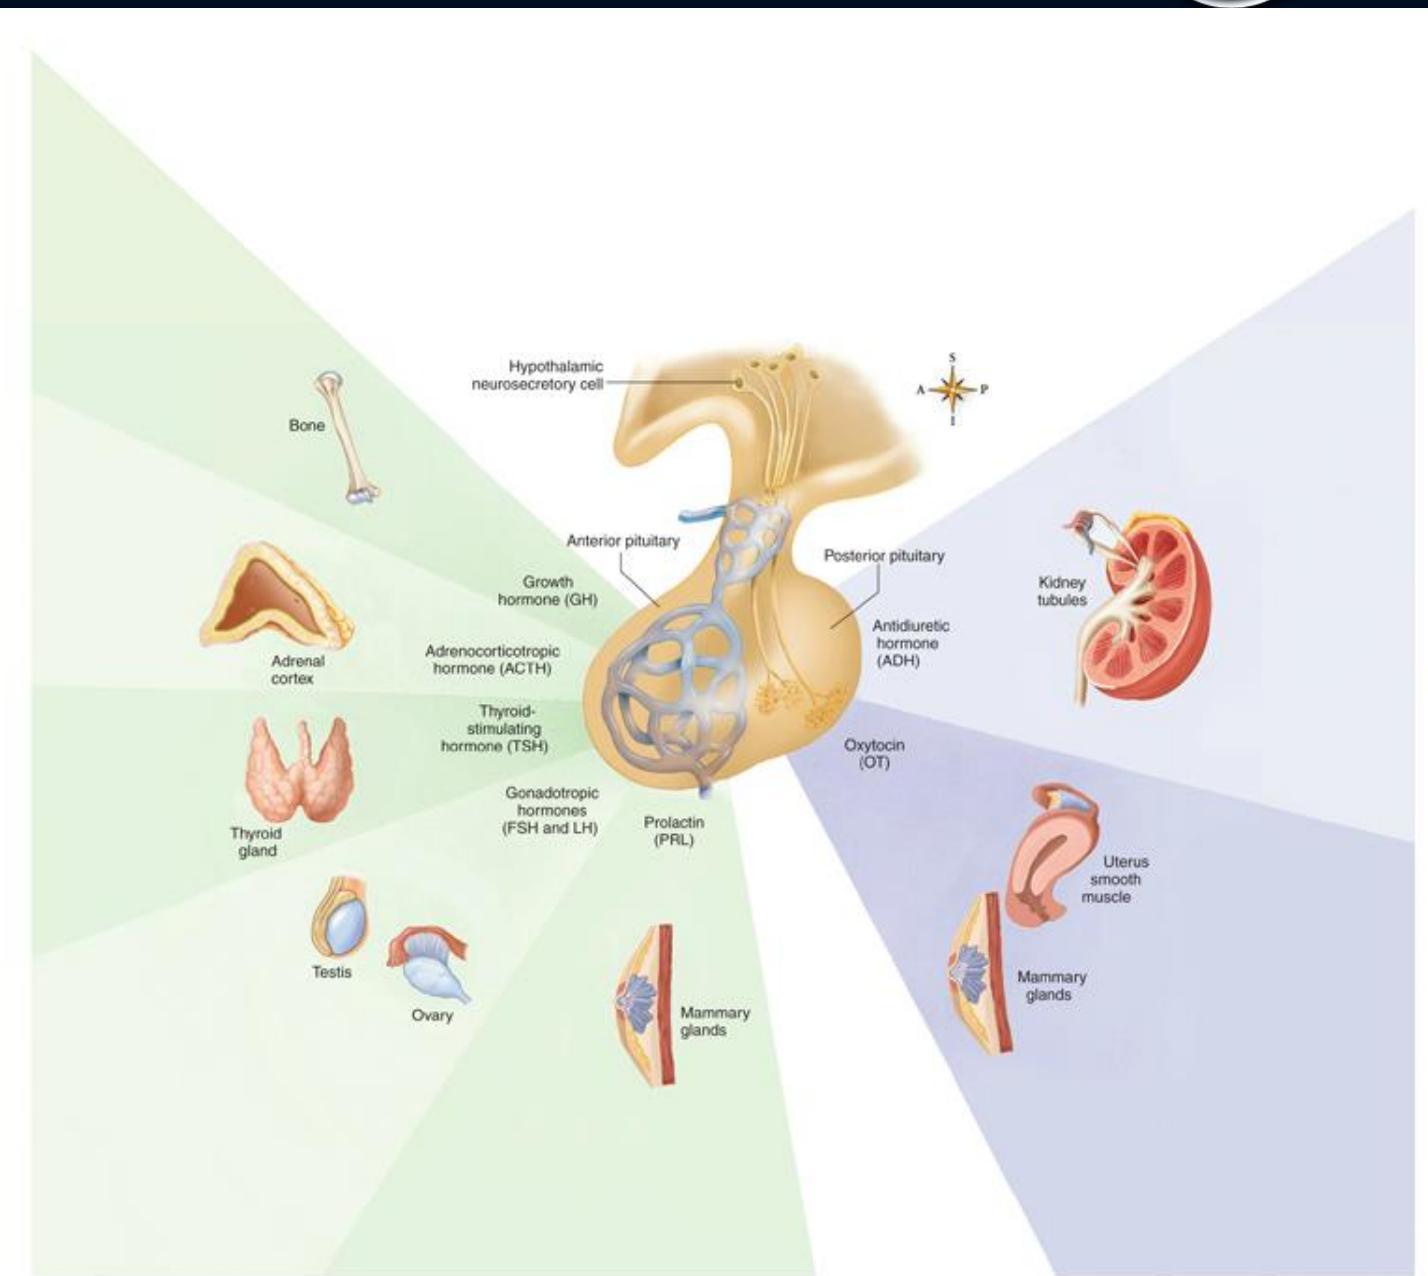

# Pineal gland

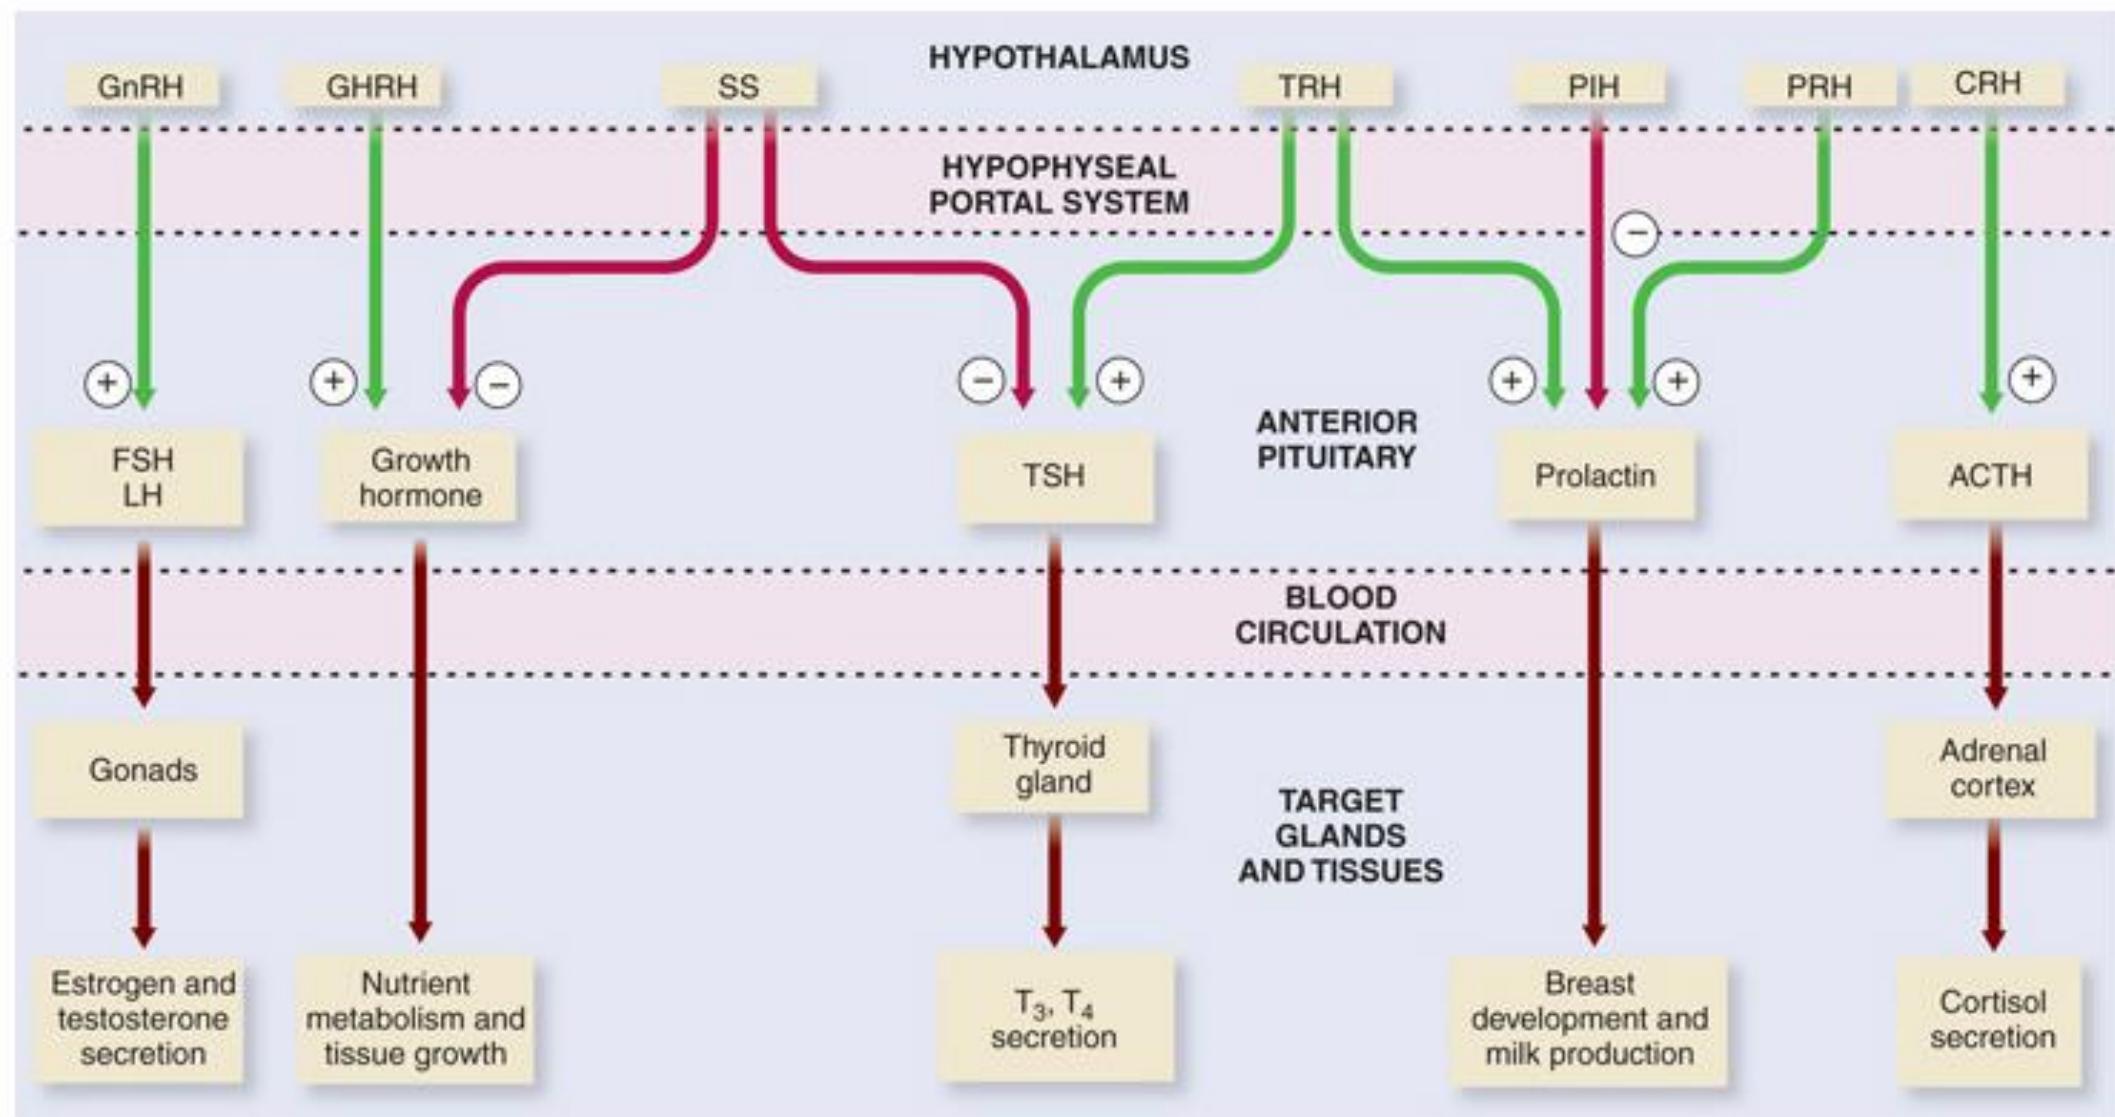

# Circadian Rhythms

- Circadian regulation of many variables
  - Temperature, blood glucose, cortisol, growth hormone, sleep cycles
- Suprachiasmatic nucleus as primary pacemaker, entrained by light dark cycles
- Light / dark information relayed to SCN through retinohypothalamic neurons
- SCN sends messages through adrenergic neurons to pineal gland which secretes melatonin
- Melatonin binds to MT<sub>1</sub> and Mt<sub>2</sub> receptors to inhibit firing of SCN neurons
  - Darkness – melatonin increases
  - Light – melatonin decreases

# Adenohypophysis vs neurohypophysis

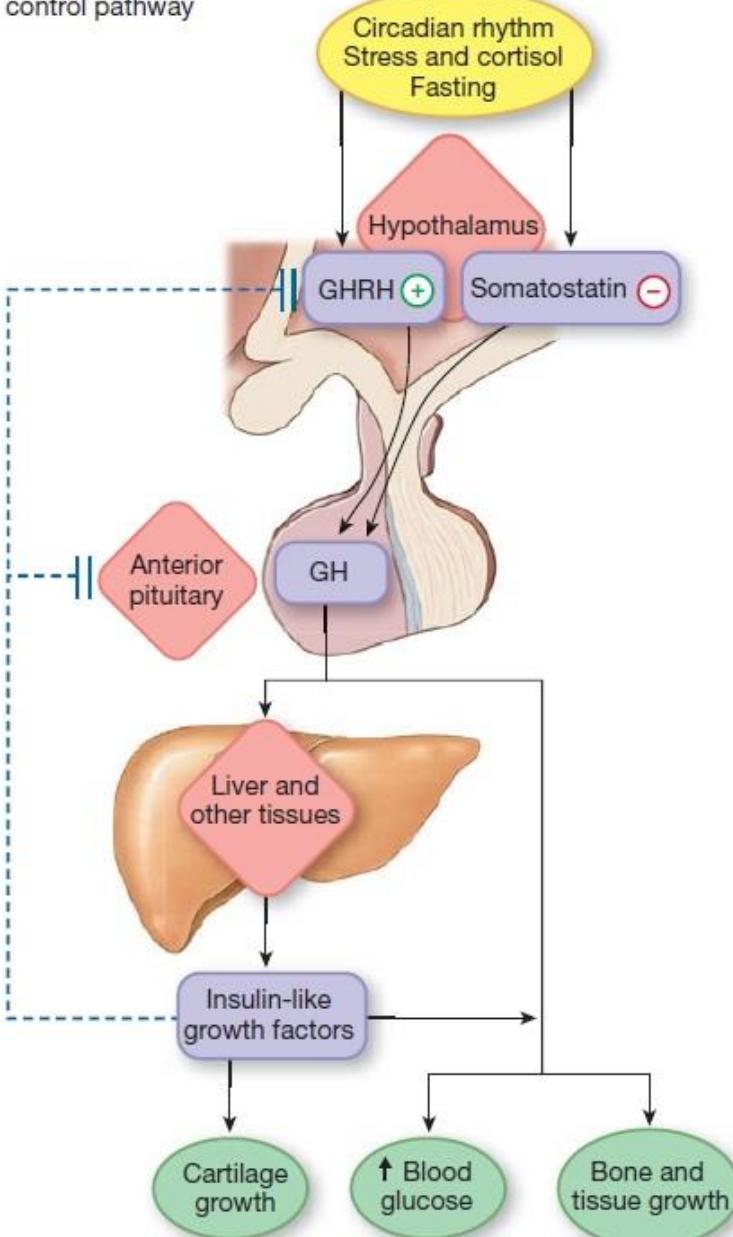

# Growth Hormone (GH) Regulation

## GROWTH HORMONE

Growth hormone control pathway

## GROWTH HORMONE (hGH)

Origin	Anterior pituitary
Chemical nature	191-amino acid peptide; several closely related forms
Biosynthesis	Typical peptide
Transport in the circulation	Half is dissolved in plasma, half is bound to a binding protein whose structure is identical to that of the GH receptor
Half-life	18 minutes
Factors affecting release	Circadian rhythm of tonic secretion; influenced by circulating nutrients, stress, and other hormones in a complex fashion
Control pathway	GHRH, somatostatin (hypothalamus) → growth hormone (anterior pituitary)
Target cells or tissues	Trophic on liver for insulin-like growth factor production; also acts directly on many cells
Target receptor	Membrane receptor with tyrosine kinase activity
Whole body or tissue reaction (with IGFs)	Bone and cartilage growth; soft tissue growth; ↑ plasma glucose
Action at cellular level	Receptor linked to kinases that phosphorylate proteins to initiate transcription

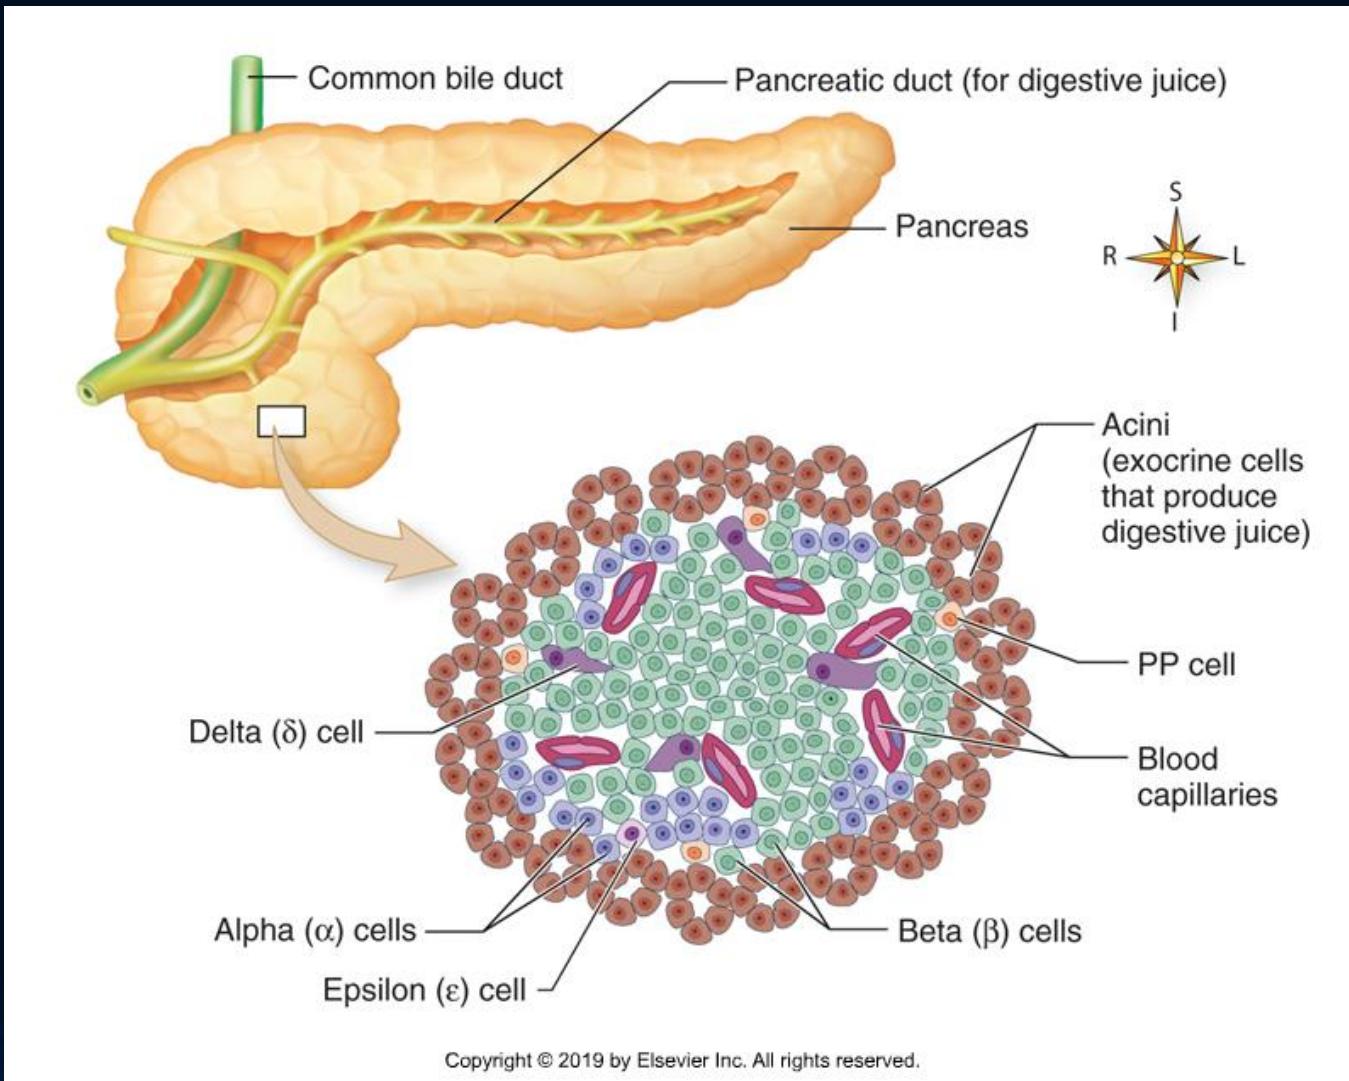

# Growth Hormone (somatotropin)

- GH Release is influenced by Growth hormone releasing hormone (somatocrinin / somatorelin) and growth hormone inhibiting hormone (somatostatin)
- Major effects of GH
  - Stimulates liver to secrete Insulin-like growth factor (IGF-1)
  - Increased  $\text{Ca}^{+2}$  retention and formation of bone matrix
  - Increased muscle mass, increased protein synthesis
  - Gluconeogenesis, decreases glucose uptake by liver
- Use in sports?

# • Pancreatic hormones

- Alpha cells – glucagon
- Beta cells – insulin
- Delta cells – somatostatin – paracrine influence on other islet cells
- Epsilon cells – ghrelin (increases appetite)
- PP Cells – pancreatic polypeptide
- Acini cells – exocrine pancreas functions

# Regulation of Blood Glucose

- Insulin – hormone of the fed state
  - Signals to release – high blood glucose, PNS
  - Actions
    - increase expression of glucose  $\_4$  transport protein
    - Increase cellular uptake and storage of lipids, amino acids and glucose as TGs, proteins and glycogen
- Glucagon – hormone of the fasted state
  - SIGNALS to release – low blood glucose, SNS
  - Actions
    - Increased Glycogenolysis
    - Increased gluconeogenesis
    - Increased secretion of glucose into blood
